Workaround: Occasionally send a synchronous message from the client to the server. The message does not have to have a return value or parameters, or do anything, but will serve to flush pended releases back to the client. Another workaround would be to occasionally invalidate the connection to the server and reconnect.

Reference: 77559

Releases: OPENSTEP 4.2

Platforms: Mach, HP-UX, Solaris

Disposition: None

Issue: Process name is empty string

Description: If argv[0] of a process is not an absolute path, and the Foundation can't find argv[0] by searching the PATH environment variable to compute the absolute path, the process name computation may result in the empty string. This can only happen if a process uses fork() and execve() (or related function) to create a Foundation-based process, and the first argument to execve() specifies an executabe which does not exist in the PATH list and the argv[0] passed into execve() is not that same full path, but a relative one. There isn't anything the Foundation can do in this case about computing the full path to the executable, for use in computing the main bundle for example. However, the process name should not be empty string, but rather the last component of argv[0] unchanged. An empty string for the process name causes trouble for other Foundation subsystems, like user defaults.

Workaround: Pass the same string in argv[0] as the first argument, to execve() or related function.

Reference: 77678

Releases: OPENSTEP 4.1

Platforms: All

Disposition: Fixed in OPENSTEP 4.2

Issue: NSNumber's -decimalValue method broken for non-English usage

Description: The -decimalValue method of NSNumber incorrectly computes its result for users whose defaults specify a decimal point other than period (`.'). This may cause NSNumberFormatters to not accept any input other than "2" in a text field. This affects the scale field in the AppKit's print panel in 4.1, for example.

Workaround: None

Published Date: Feb 20, 2012

OPENSTEP 4.2 Release Notes: Project Builder

This file contains release notes for the Project Builder application distributed with OpenStep 4.2. It includes information specific to OPENSTEP for Mach and to OPENSTEP for Windows as well as information general to both platforms.

Project Builder provides integrated code development capabilities for the sophisticated developer. Its main window combines a project browser with a full-featured code editor. You can bring up panels for building, debugging, finding information in the project, and setting project attributes. To familiarize yourself with Project Builder's capabilities and features, you can do one of the following"

- ·On Mach, choose the Help command from Project Builder's Info menu. This launches a Digital Librarian bookshelf containing the on-line book OpenStep Development: Tools and Techniques.
- ·On Windows, choose the How To command from Project Builder's Help menu. This launches a Windows Help version of the same book.

This article has been archived and is no longer updated by Apple.

New Features for 4.2

Click-to-Find Button

A new context help button has been added to the right of the toolbar. It activates the context help mode, denoted by the question-mark cursor. In context help mode, you can get information on UI items by clicking on them. You can also use this button for "Click-To-Find" operations to access symbols in the project's index. To get definitions for source code symbols, move the cursor over the source file and click when the symbol has been highlighted. This will bring up the finder panel to display the results.

Fuzzy Indexing

A new lighter-weight style of project indexing debuts in this release on both Mach and Windows. It provides a more reliable and low-cost index that is not based on the strict pre-processing and formal parsing methodology employed in 4.0 and 4.1 (which is only available on Mach via a defaults setting). In addition to using less virtual memory and CPU time, the fuzzy parsing system can index symbols inside #ifdefs that are not currently turned on in your builds.

Information about frameworks is shared across projects that link against them and can be accessed from the project find panel associated with each such projects. Information about other header files you may import is not currently stored. All existing preferences, indexing panel operations, and find panel queries now apply to the new Fuzzy Indexing feature.

Framework Documentation Access

Although the Find panel can be used to access documentation about a particular symbol, all of the documentation associated with a framework can now be browsed. The Frameworks suitcase will now show for each framework the on-line available documentation structure. This works as a direct link to the file system with the use of filtering. On Mach, the user can browse the documentation and display any file directly from the project browser. On Windows, the WinHelp system can be launched on a particular framework's documentation.

Syntax Coloring

It is now possible to use syntax coloring on source files (C, C++, Obj-C, Java). Syntax coloring is a feature that allows Project Builder to show parts of a source file (tokens) using different text attributes depending on their meaning. For instance, comments can appear in italic text and string constants in red.

A new "Syntax Coloring" preferences pane has been added to allow you to switch the syntax coloring off or change the font and color for each lexical category of text.

The current set of lexical categories include: Comments, Keywords, Strings, and Numbers. It is also possible to use the normal text attributes for a lexical category inherited from the existing "Fonts, Sizes & Colors" preferences pane. Tokens that don't appear in one of the lexical categories (such as identifiers) will always inherit these default attributes. Switching syntax coloring on and off takes place right away. Setting attributes for one or more tokens "dirties" the window; these settings are applied and saved to the defaults when Set is pressed. Revert takes you back to the previously-saved syntax-coloring preferences.

Improved Debugging

A number of bugs have been fixed in the Launcher/Debugger facilicities of Project Builder. New features include the ability to set the directory paths needed for dynamically loaded libraries and, on Windows, better integration between building and debugging an executable. When a path is entered in the Launcher Options Panel environment section, the Launcher sets the appropriate environment variable so that launched and debugged programs use dynamically-loaded libraries located in the specified directory. When building a project on Windows, the final link of the executable will fail if the executable is being run or debugged. Project Builder will now ask you if you want to stop a launched executable when building. If the executable is being debugged, Project Builder will notify gdb to release the executable and then reload its symbols when the build finishes. While the build is in progress, you cannot run the executable from within the debugger, but you can manipulate breakpoints.

New Features for 4.1

New Makefiles

Project Builder includes new makefiles that offer several advantages over the previous ones. These makefiles:

- Build projects with lower overhead.
- Fix a number of extensibility problems.
- Allow a higher degree of parallelism with gnumake -j.
- Make it easier to diagnose problems.

When you first open a project that uses the old makefiles, Project Builder displays a panel that lets you do one of the following:

- Convert immediately to the new makefiles.
- Keep your current makefiles.
- Defer the decision to later.

If you convert to the new makefiles, the project defines this path to them in MAKEFILEDIR:

$NEXT_ROOT/NextDeveloper/Makefiles/Project Builder_makefiles

The original 4.0 Makefiles are located in this directory:

$NEXT_ROOT/NextDeveloper/Makefiles/project

Currently, you can override the MAKEFILEDIR attribute for your project in Makefile.preamble by setting it to the desired directory. Or you can edit the MAKEFILEDIR attribute in Project Builder.project, but not through the user interface of Project Builder. You are strongly encouraged to convert your projects to the new makefiles if that is feasible. For instance, a new facility that automatically generates .def files (see below) depends on these makefiles. However, you might keep older makefiles intact for those exceptional projects that depend upon unique implementation details in the project makefiles.

Microsoft Linker

The Microsoft linker is now the default for projects on Windows built with Project Builder. This is the same linker that ships with the current Visual C++. For information on using the linker, consult the Visual C++ documentation. See the following item, "Automatic Generation of .def Files," for a related issue.

Automatic Generation of .def Files

On WIndows, the Microsoft linker requires symbols exported from a framework DLL to be explictly specified. One way of doing this is in a .def file in the project (for example, "MyFramework.def"). In prior releases, this file had to be manually created. Project Builder now generates a .def file for frameworks and dynamic libraries (that is, library projects producing DLLs). It re-creates the file the first time a project is built and, thereafter, updates it every time an object file changes. To get this feature, you must update to the new makefiles (See "New Makefiles," above).

If you currently have a .def file for a framework, and it is not highly customized, delete it and let Project Builder regenerate it for you. Otherwise, leave it where it is. Project Builder creates a .def file only if there isn't one already in the project.

The .def file that Project Builder creates is comprehensive, so if you want to create a customized .def file that is a subset of it, first build your project. Then add the generated .def file in derived_src to Supporting Files in your project and edit it as necessary.

Note: You should use the CONSTANT keyword instead DATA in your .def file. The export of framework functions also requires a little extra code. For more on both of these items, see "Known Problems in this Release, " below.

In creating the .def file for frameworks and dynamic libraries (DLLs), Project Builder handles Objective-C symbols and data but not functions. If you have functions in your framework that need to be callable from the outside, define certain macros in a header file and then use them in your function declarations. These macros allow you to export non-static functions from the DLL (FRAMEWORK_EXTERN) or to declare them as extern, but not exported (FRAMEWORK_PRIVATE_EXTERN). The following example shows how (substitute your own framework name for FRAMEWORK):

```
#ifndef _FRAMEWORKDEFINES_H

#define _FRAMEWORKDEFINES_H

#if defined(WIN32)

//

// For Windows

//

#ifndef _FRAMEWORK_BUILDING_DLL

#define _FRAMEWORK_WINDOWS_DLL __declspec(dllimport)

#else

#define _FRAMEWORK_WINDOWS_DLL __declspec(dllexport)

#endif

#ifdef __cplusplus

#define FRAMEWORK_EXTERN extern "C" _FRAMEWORK_WINDOWS_DLL

#define FRAMEWORK_PRIVATE_EXTERN extern

#else

#define FRAMEWORK_EXTERN _FRAMEWORK_WINDOWS_DLL extern

#define FRAMEWORK_PRIVATE_EXTERN extern

#endif
```

You need to import this header in all your other headers and declare your function prototypes accordingly. Then make sure you define FRAMEWORK_BUILDING_DLL when building your framework.

New Features for 4.0

Some or all of these new features may exist in the Windows version of Project Buiilder depending on its state at the time of the release:

- The new Launcher Panel allows you to run or debug executables built by the project.
- Printing is now supported.
- The Build Attributes Inspector allows you to specify OS specific values for compiler flags, linker flags, installation and build directories, and build tool.
- The Build Options panel values persist across invocations of Project Builder. The values you specify on this panel are saved per-user, per-project.
- In the Project Attributes Inspector for an application project, you can specify a help file and icons for both NT (.ico, .ICO) and Mach (.eps, .tiff).
- Project Builder by default sets tab stops at regular intervals of eight spaces each. There is now a dwrite, ªtabStopCharsº, that allows you alter this interval to any desired number of spaces, as long as that number is greater than zero.

Converting 3.x applications to 4.x

The _main.m files of 3.x applications have to be manually converted to the new _main.m content. To do this, copy the main() code from existing 4.1 projects or create a new project and copy its main() code. You can also copy and paste this code directly from here:

```
#import <AppKit/AppKit.h>

int main(int argc, const char *argv[]) {

return NSApplicationMain(argc, argv);

}
```

Known Problems in The 4.2 Release < Mach and Windows

These problems are known to exist with this release on both Mach and Windows:

Reference: 76564

Problem: Files containing C++ constructs are not indexed

Description: The symbol index is not built for source code modules that contain C++ code or for .h files that appear to contain declarations specific to C++. As well, reference queries do not work in the project find panel.

Reference: 76321

Problem: Project Builder edit caches file changes in memory between close and reopen of a project

Description: If you choose not to save changes to a file when closing a project, when the project is opened again Project Builder reuses the file buffer containing the unsaved changes for that file, instead of the version of the file from the disk

Reference: 76133

Problem: File renaming doesn't work properly

Description: Using the Inspector to change the name of a file causes exceptions to be raised inside Project Builder.

Reference: 76114

Problem: Yellow arrows are not displayed in the browser

Description: If you open a file and then index the project, the yellow arrow, which signifies the file is indexed, is not displayed for that file. The arrows are displayed for other files.

Reference: 77979

Problem: LIBRARY_STYLE=STATIC excludes frameworks

Description: If your builds terminate with link errors claiming that imported frameworks are undefined, check your Makefile.preamble to see if the following line is uncommented.

LIBRARY_STATIC = STYLE

If it is uncommented, prepend a hash character (#) to comment it out. Due to a change in the make process, "LIBRARY_STYLE=STATIC" tells the linker not to link against frameworks (such as AppKit and Foundation), even if they are added to the project.

Known Problems in The 4.2 Release < Windows

These problems are known to exist with this release on Windows:

Reference: 69061

Problem: Builds will fail if NEXT_ROOT has been modified to contain backward slashes.

Description: The installer specifies NEXT_ROOT with forward slashes, for example:

C:/NeXT/

Do not edit this variable in the Environment section of the System control panel, even if to change the forward slashes to backward slashes.

Reference: 72307

Problem: The Microsoft linker emits a bogus warning about CONSTANT keywords.

Description: When you build framework projects, you will see messages complaining about the use of CONSTANT keywords in your .def file. Because of problems with the linker, CONSTANT should be used in place of DATA. You can ignore the warnings.

Reference: 76192

Problem: Find results don't show the documentation icon for methods.

Description: After indexing the project, a find on a method name does not show the documentution icon

(a book) for methods which have documentation.

Reference: 75239

Problem: Project Builder thinks some .nib files have been modifed

Description: Open a project and then start Interface Builder. Open a .nib file with Interface Builder, not by double-clicking on the nib inside Project Builder. Build the project in Project Builder and Project Builder will warn that the .nib file is modified, when it is not. The workaround is to start Interface Builder by double-clicking the nib inside Project Builder.

Known Problems in The 4.2 Release < Mach

These problems are known to exist with this release on Mach:

Reference: 67785

Problem: Breakpoints on functions or methods without debugging information aren't displayed in the breakpoint inspector.

Reference: 67712

Problem: Moving a breakpoint icon doesn't update the line number in the Breakpoint inspector. However, the location of the breakpoint is updated in gdb.

Published Date: Feb 20, 2012

OPENSTEP 4.2 Release Notes For Pre-4.0 Foundation Users

In the document below, "4.0" and "OPENSTEP 4.0" refer to all products that shipped with the 4.0 Foundation: OPENSTEP 4.0, D'OLE 4.0, and PDO 4.0 for HP-UXTM and SolarisTM.

There were several releases of the Foundation Framework prior to OPENSTEP 4.0. Foundation shipped with:

- NEXTSTEP 3.3
- Enterprise Objects Framework 1.0
- Enterprise Objects Framework 1.1
- Portable Distributed Objects 3.0
- D'OLE 3.5
- OPENSTEP 4.0 Prerelease 1
- OPENSTEP 4.0 Prerelease 2
- PDO 4.0 Prerelease

This document only describes API changes that have been made between those releases and OPENSTEP 4.0. (For changes since OPENSTEP 4.0, see the release note Foundation.rtf.) The semantics of many things have changed, but most not in a way that will affect programs (NEXTSTEP 3.3 Foundation-based programs and EOF 1.1 programs, being older, are more likely to be affected). Unfortunately, there is no single source for information about such changes±refer to the Foundation Framework Reference and specific class specifications for the current behavior. This document does not describe extensions to Foundation provided by various NeXT products (for example, WebObjects or EOF).

Foundation is now packaged as a ProjectBuilder framework, and resides in /NextLibrary/Frameworks/Foundation.framework. The headers can be found in /NextLibrary/Frameworks/Foundation.framework/Headers.

All programs based upon previous version of Foundation should be recompiled (even if no conversion is necessary) to function with this version of Foundation. Compiling against the old static "shlib" (the shared library shipped with NEXTSTEP 3.3, EOF 1.1, and PDO 3.0, and used by WebObjects) is not supported in OPENSTEP 4.0 (without EOF 1.1 installed).

This section is divided into a subsection for each of the previous releases of the Foundation Framework. There are no specific notes for Enterprise Objects Framework 1.0, Portable Distributed Objects 3.0, or WebObjects 1.0 developers; please refer to the section for Enterprise Objects Framework 1.1 developers. The API of the Foundation shipped with Portable Distributed Objects 3.0 and WebObjects 1.0 was identical to that in Enterprise Objects Framework 1.1 (other than extensions made by those products).

This article has been archived and is no longer updated by Apple.

Notes Specific to NEXTSTEP 3.3 Developers

Items in the tables below (in the section titled **Tables Showing Foundation API Changes**) that are marked with "(NS33)" are changes made to Foundation between NEXTSTEP 3.3 and OPENSTEP 4.0. Also see the general comments in the section Notes Specific to Enterprise Objects Framework 1.1 Developers below. NEXTSTEP 3.3 developers should note the following additions to those comments:

- The header NXAutoreleaseConnection.h was not in NEXTSTEP 3.3. Comments referring to this header do not apply to NEXTSTEP 3.3 developers.
-
- Two additional headers, NSLock.h and NSThread.h, were not in NEXTSTEP 3.3, but are in OPENSTEP 4.0.

Notes Specific to Enterprise Objects Framework 1.1 Developers

Items in the tables below (in the section titled **Tables Showing Foundation API Changes**) marked with "(EOF11)" are changes made to Foundation between EOF 1.1 and OPENSTEP 4.0.

Some additional changes are not contained in the tables or are of particular note:

- Headers are now imported as <Foundation/...>, rather than <foundation/...>.
- The structure of imports has changed. The Foundation headers import all ANSI C headers they need and some of the Objective-C interfaces, but none of the operating system interfaces. The set of headers imported by each header has also changed in many places. Where a project was getting a header imported "for free" before, it may now need to import additional headers in order to compile.
- The header NXAutoreleaseConnection.h has been removed. Its contents have been moved to NSCompatibility.h.
- A Foundation.h header has been added, which includes the 15 ANSI C headers, and all Foundation headers except NSCompatibility.h and NSDebug.h.
- The top-level NSAutoreleasePool is no longer created for automatically±a program needs to create it itself. See the Foundation Framework Reference and the NSAutoreleasePool class specification for more information on creating autorelease pools.
- NSDictionary no longer constrains keys to be instances of NSString. Any object that meaningfully responds to -hash, -isEqual:, and -

copyWithZone: can be an NSDictionary key.

- The name of the exception variable in the NS_HANDLER...NS_ENDHANDLER region has been changed from exception to localException.
- Some methods that are not in OpenStep, and were not guarded with #if !defined(STRICT_OPENSTEP), now are guarded.
- NSObject no longer conforms to the NSCoding protocol. Instead, the classes that can be archived or distributed, and their subclasses, conform to the protocol explicitly.
- NSBundle's and NSNotificationCenter's instance variables are now declared @private.
- The type of the parameter to NSBundle's +bundleForClass: method changed from id to Class.
- The type of the parameter to NSValue's +valueWithPointer: method changed from void * to const void *.
- The typedef NSStringEncoding in NSString.h has changed from a typedef'd enumeration to a typedef'd scalar.
- The value of the enumeration constant NSUnicodeStringEncoding in NSString.h has changed from 0 to 10.
- The location of the resources has changed, and can now be found in the Foundation framework directory. If, in a previous release of the Foundation, your application was poking around in the Foundation resources, you should carefully consider why you were doing so, and stop doing it if possible.
- The declarations of the NSAutoreleasePool debugging methods and aids have moved from NSAutoreleasePool.h to NSDebug.h. Some of the methods are destined for obsolescence, and some new methods have been added.
- The header NSObjCRuntime.h now imports the headers objc/zone.h and stdarg.h.
- Many declarations and definitions were removed from the header NSUtilities.h and moved elsewhere, but all the previous material is still defined by importing NSUtilities.h. The headers to which things were moved are NSEnumerator.h, NSObjCRuntime.h, NSDictionary.h, and NSString.h.

Finally, the Foundation shipped with EOF 1.1 did not contain much of the functionality of the Foundation in OPENSTEP 4.0. These headers, and all the API they declare, were added between EOF 1.1 and OPENSTEP 4.0:

```
NSAttributedString.h
NSFormatter.h
NSPPL.h
NSByteOrder.h
NSGeometry.h
NSProcessInfo.h
NSCompatibility.h
NSHashTable.h
NSProtocolChecker.h
NSConnection.h
NSHost.h
NSProxy.h
NSDateFormatter.h
NSInvocation.h
NSRunLoop.h
NSDebug.h
NSMapTable.h
NSSerialization.h
NSDecimal.h
NSMethodSignature.h
NSSet.h
NSDecimalNumber.h
NSNotificationQueue.h
NSTask.h
NSDistantObject.h
NSNumberFormatter.h
NSTimer.h
NSDistributedLock.h
NSPort.h
NSUserDefaults.h
NSEnumerator.h
NSPortCoder.h
NSFileHandle.h
NSPortMessage.h
NSFileManager.h
NSPortNameServer.h
```

The API added by these headers is not included in the tables below.

Notes Specific to D'OLE 3.5 Developers

Items in the tables below (in the section titled Tables Showing Foundation API Changes) marked with "(40PR1)" are changes made to Foundation between OPENSTEP 4.0 PR1 and OPENSTEP 4.0. This symbol also marks changes that apply to D'OLE 3.5 developers, with the exceptions noted below. See also the general comments in the section Notes Specific to OPENSTEP 4.0 PR1 Developers below.

The following are exceptions to the changes noted between OPENSTEP 4.0 PR1 and OPENSTEP 4.0, for D'OLE 3.5 developers:

- The header NSPPL.h isn't in D'OLE 3.5, but is in OPENSTEP 4.0. API changes referring to this header do not apply to D'OLE 3.5 developers.
- These methods were in D'OLE 3.5, but not in OPENSTEP 4.0 PR1:

CLASS	HEADER	METHOD	
NSString	NSPathUtilities.h	+pathWithComponents:	(+NeXT) (40PR1)
NSString	NSPathUtilities.h	-isAbsolutePath	(+NeXT) (40PR1)
NSString	NSPathUtilities.h	-pathComponents	(+NeXT) (40PR1)

Notes Specific to OPENSTEP 4.0 PR1 Developers

Items in the tables below (in the section titled Tables Showing Foundation API Changes) marked with "(40PR1)" are changes made to Foundation between OPENSTEP 4.0 PR1 and OPENSTEP 4.0.

Some additional changes are not contained in the tables or are of particular note:

- All applications, frameworks, libraries, bundles, tools, etc. compiled in PR1 should be recompiled.
- The header file NSAccount.h has been removed from Foundation. This header was NeXT-specific.
- The header file NSByteStore.h has been removed from Foundation (both from OpenStep and from NeXT's implementation).
- The import of the header NSDebug.h has been removed from Foundation.h; however, it still exists. This header contains features intended for debugging, but not for general use.
- Foundation.h now imports the 15 ANSI C headers (assert.h, ctype.h, errno.h, float.h, limits.h, locale.h, math.h, setjmp.h, signal.h, stdarg.h, stddef.h, stdio.h, stdlib.h, string.h, time.h) as a convenience.
- The header file NSObjCRuntime.h imported six obsolete headers (ansi/ansi.h, objc/typedstream.h, objc/objc-class.h, architecture/byte_order.h, objc/hashtable.h, streams/streams.h) in PR1. It no longer does so. This change may mean that some of these headers may need to be explicitly imported for code written on OPENSTEP 4.0 PR1 to recompile.
- A STRICT_OPENSTEP preprocessor guard now surrounds all API in the headers NSDecimal.h and NSDecimalNumber.h.
- The macro FOUNDATION_EXPORT is now always explicitly defined on WindowsTM (that is, it cannot be predefined with the -D compiler option) in NSObjCRuntime.h.
- A new header and related functionality, NSTask.h, was added.
- See also changes noted in the section Notes Specific to OPENSTEP 4.0 PR2 Developers. All changes listed apply to OPENSTEP 4.0 PR1 developers.

Notes Specific to OPENSTEP 4.0 PR2 Developers

Items in the tables below (in the section titled Tables Showing Foundation API Changes) marked with "(40PR2)" are changes made to Foundation between OPENSTEP 4.0 PR2 and OPENSTEP 4.0.

Some additional changes are not contained in the tables or are of particular note. This list of changes applies to both OPENSTEP 4.0 PR1 and PR2 developers:

- The size of NSPort and NSRunLoop instances has changed. The NSPort class has become abstract and no longer has any instance variables. Applications, tools, frameworks, bundles, or libraries with subclasses of these two classes must be recompiled.
-
- The header file NSPosixFileDescriptor.h has been removed from Foundation. This header was NeXT-specific. The header NSFileHandle.h provides portable replacement functionality.
-
- A few new headers have been added. The API in these headers is not included in the tables below:

```
NSAttributedString.h
NSFormatter.h
NSDateFormatter.h
```

```
NSNumberFormatter.h
NSEnumerator.h
NSProtocolChecker.h
NSFileHandle.h
```

- Many declarations and definitions were removed from the header NSUtilities.h and moved elsewhere, but all the previous material is still defined by importing NSUtilities.h. The headers to which things were moved are NSEnumerator.h, NSObjCRuntime.h, NSDictionary.h, and NSString.h.
- The header NSObjCRuntime.h now imports the headers objc/zone.h and stdarg.h.
- The type of the parameter to NSTask's -setStandardInput:, -setStandardOutput:, and -setStandardError: methods has changed from NSPosixFileDescriptor * to id.
- The declarations of the NSAutoreleasePool debugging methods and aids have moved from NSAutoreleasePool.h to NSDebug.h. Some of the methods are destined for obsolescence, and some new methods have been added.
- These methods are no longer declared on WindowsTM platforms:

CLASS	HEADER	METHOD
NSDictionary	NSFileManager.h	-fileSystemFileNumber
NSDictionary	NSFileManager.h	-fileSystemNumber
NSFileManager	NSFileManager.h	-createSymbolicLinkAtPath:pathContent:
NSFileManager	NSFileManager.h	-pathContentOfSymbolicLinkAtPath:

- Although they are still declared on WindowsTM, an application should not use the string constants NSFileSystemNumber or NSFileSystemFileNumber, either.

Notes Specific to PDO 4.0 PR1 Developers

Items in the tables below (in the section titled Tables Showing Foundation API Changes) marked with "(P40PR1)" are changes made to Foundation between PDO 4.0 PR1 and OPENSTEP 4.0 and PDO 4.0.

Some additional changes are not contained in the tables or are of particular note:

- The Foundation is now shipped as a shared library in PDO 4.0 for SolarisTM. All applications, tools, frameworks, bundles, libraries, etc. should be recompiled to take advantage of this.
- The size of NSPort and NSRunLoop instances has changed. The NSPort class has become abstract and no longer has any instance variables. Applications, tools, frameworks, bundles, or libraries with subclasses of these two classes must be recompiled.
- The header file NSPosixFileDescriptor.h has been removed from Foundation. This header was NeXT-specific. The header NSFileHandle.h provides portable replacement functionality.
- A few new headers have been added. The API in these headers is not included in the tables below:

```
NSAttributedString.h
NSFormatter.h
NSDateFormatter.h
NSNumberFormatter.h
NSFileHandle.h
NSProtocolChecker.h
```

- The type of the parameter to NSTask's -setStandardInput:, -setStandardOutput:, and -setStandardError: methods has changed from NSPosixFileDescriptor * to id.

Tables Showing Foundation API Changes

There are four tables that list the API changes between previous versions of Foundation and the version of Foundation in OPENSTEP 4.0. The first table lists general changes to API elements (classes, macros, functions, constants, and so on) except methods, the second table lists the changes to the set of methods offered by the classes in Foundation, the third table lists changes to the return values of methods (for methods that didn't change name, which are listed in the second table), and the fourth table lists changes in the location of declarations. Other miscellaneous changes that weren't described well in table format are given in the sections above.

Changes are noted from the perspective of a developer who used a previous release looking to port their Foundation-based code to OPENSTEP 4.0 (and not through any intermediate releases). For instance, changes that are marked as having been made between OPENSTEP 4.0 PR1 and PR2 do not necessarily apply to NEXTSTEP 3.3 developers (for example, an API might have been added for OPENSTEP 4.0 PR1, but removed for OPENSTEP 4.0 PR2).

The rows in the tables are marked with various symbols in the rightmost column. One set of symbols describes between which releases and OPENSTEP 4.0 the change was made:

(NS33) Change occurred between NEXTSTEP 3.3 and OPENSTEP 4.0

(EOF11) Change occurred between EOF 1.1 and OPENSTEP 4.0

(40PR1) Change occurred between OPENSTEP 4.0 PR1 and OPENSTEP 4.0

(40PR2) Change occurred between OPENSTEP 4.0 PR2 and OPENSTEP 4.0

The other set of symbols indicate how the API changed. Both NeXT's implementation of Foundation, and the OpenStep specification (since version 1.0 was published) have changed. These symbols attempt to describe what has happened:

(OpenStep,NeXT) Generically, a change that did not add or remove API, but affects OpenStep and NeXT's implementation

(OpenStep) Generically, a change that did not add or remove API and affects OpenStep, but not NeXT's implementation

(NeXT) Generically, a change that did not add or remove API and affects NeXT's implementation, but not OpenStep

(+OpenStep,+NeXT) Was in neither OpenStep nor NeXT's implementation, now in both

(+OpenStep,NeXT) Was in NeXT's implementation only, now also in OpenStep

(+OpenStep,-NeXT) Was in NeXT's implementation only, now in OpenStep only

(OpenStep,+NeXT) Was in OpenStep only, now also in NeXT's implementation

(OpenStep,-NeXT) Was in both, now in OpenStep only

(-OpenStep,+NeXT) Was in OpenStep only, now in NeXT's implementation only

(-OpenStep,NeXT) Was in both, now in NeXT's implementation only

(-OpenStep,-NeXT) Was in both, now in neither

(+OpenStep) Was in neither OpenStep nor NeXT's implementation, now in OpenStep only

(-OpenStep) Was in OpenStep only, now in neither

(+NeXT) Was in neither OpenStep nor NeXT's implementation, now in NeXT's implementation only

(-NeXT) Was in NeXT's implementation only, now in neither

Occasionally, to the right of the rightmost column is a note for removed API which names the replacement.

OPENSTEP 4.2 Release Notes

With every release of its software, NeXT provides notes containing information pertaining to the release. These notes apply to Releases 4.2 and 4.1, and in some cases to earlier releases as well.

These on-line Release Notes list new features, fixed bugs, and known bugs that will be of interest to developers using OPENSTEP‰ for Mach, OPENSTEP Enterprise, and PDO. These notes incorporate the latest known information about the release, and are thus more current than those found on the OPENSTEP Enterprise CD-ROM.

This article has been archived and is no longer updated by Apple.

About This Release

Release 4.2 is primarily a bug-fix release. In addition, numerous fixes and enhancements have been made to the development tools, and the compilers have been synched-up so that they use the same source base across NeXT's entire product line (OPENSTEP for Mach, OPENSTEP Enterprise, and PDO). Release 4.2 also supports Windows 95 as a deployment platform (debugging is supported, but compilation is not). Windows 95 is not supported for applications that use Apple's WebObjects frameworks, or any other feature of WebObjects not otherwise included in OPENSTEP Enterprise.

The various files containing release notes for developers are listed below. These files are included in the ªDeveloper Release Notesº target of the NEXTSTEP Developer bookshelf (in the directory /NextLibrary/Bookshelves), and are located in /NextLibrary/Documentation/NextDev/ReleaseNotes.

This file is divided into the following major sections:

- Installation--Important notes regarding product installation
- Compiler--The C, Objective-C, and C++ compilers
- CompilerTools--Assembler, Linker, and other compiler-related tools
- Converting Your Code--Converting your code from NEXTSTEP to OPENSTEP
- Debugging--The GNU Source-level Debugger
- Documentation--Locating on-line documentation
- DriverDevelopment--Developing device drivers
- D'OLE--The D'OLE ORB
- EnterpriseObjects--The Enterprise Objects Framework, Release 2.1
- ProjectBuilderSCM--Software Configuration Management extensions to Project Builder
- Supplemental User Notes--Notes applicable to deployment systems as well as development systems
- TextEdit--The TextEdit application

The following topics are release noted in separate documents:

- AppKit--The Application Kit framework
- FoundationPre40--Describes API changes that were made between OPENSTEP 4.0 and earlier releases. This note will be of interest only if you are upgrading an application to this release from a release of OPENSTEP, PDO, or D'OLE prior to 4.0.
- Foundation--The Foundation Framework
- ProjectBuilder--Project Builder

Installation

Upgrading from OPENSTEP 4.1 for Mach

Certain hardware configurations appear to cause upgrader to fail (installation hangs, and OPENSTEP is corrupted) when upgrading an OPENSTEP 4.1 system to OPENSTEP 4.2. This issue appears to occur on systems that have EIDE CD-ROM or hard drives, and affects upgrades performed either from a CD-ROM or over a network. It appears that you can work around this issue by placing a disk in the CD-ROM drive before attempting the upgrade.

If you encounter this issue, you'll need to install OPENSTEP 4.2 from scratch.

This issue does not occur when upgrading from NEXTSTEP 3.3.

Installing on Windows 95

While this release of OPENSTEP Enterprise now supports deployment on computers running Windows, 95, these same computers cannot be used to develop OPENSTEP software. (OPENSTEP software developed on Windows NT can be deployed on Windows 95.)

See the OPENSTEP Enterprise Installation Guide for instructions on installing the deployment packages (located in the OEDeploy directory on your OPENSTEP Enterprise 4.2 CD-ROM) on computers running either Windows 95 or Windows NT.

PDO Installation

Due to a possible bug in the SPARC's quad-precision emulation software, this release cannot be used on SPARCstation 5-class machines.

Installing on Japanese Language Systems

Attempting to do a ªtypicalº installation of the NT Server Deployment (OEMinSys) package on a Japanese language system will cause the installer to enter an infinite loop. If you need to install this package on a Japanese language system, choose "custom" when asked whether you want a ªtypicalº or ªcustomº installation. When presented with the components to install, de-select ªIMEº and proceed with the installation.

This issue doesn't arise on non-Japanese systems; nor does it arise when installing either the NT Deployment (OEDeploy) or NT Development (OEDev) packages.

Known Issues in This Release

This section lists important issues that were discovered after the CD-ROM was duplicated.

Building Bundles With PDO on Solaris

Although NSBundles now work in PDO 4.2 on Solaris, due to a makefile issue bundles don't build properly (an error occurs when linking). This issue can be fixed by updating bundle.make (in

/NextDeveloper/Makefiles/pb_makefiles) and libtool (in /NextDeveloper/bin). New versions of these files can be obtained through NeXTanswers; request NeXTanswer #2499 for the updated files.

Compiler

This file contains developer release notes for the 4.2 release of the compiler.

In the 4.2 OPENSTEP Enterprise, OPENSTEP for Mach, and PDO releases, the compilers on Mach, Windows and PDO are based on the GNU C compiler version 2.7.2.1 and are all built from a single source code base.

Notes From Release 4.2

Calling superclass methods from within a category (78005)

In the 4.2 prerelease, the Objective-C++ compiler would crash when processing code that called a superclass method from within a category. While this bug has been fixed in the final version of OPENSTEP 4.2 Developer for Mach, it still exists in the compilers included with OPENSTEP Enterprise 4.2. Thus, if you're using the Objective-C++ compiler and your category implementations call superclass methods, your code will compile on Mach but not on Windows NT or PDO. Note that this code will compile on Windows NT or on PDO if you use the Objective-C compiler.

Change in meaning of extern "C" to C++ compiler

The C++ and Objective C++ compilers no longer switch the list of valid keywords when they see the extern "C" construct. This may cause existing C++ and Objective C++ code to fail to compile. The extern "Objective-C" construct can still be used, as in the past, to switch to a mode in which C++-specific keywords such as "class" and "template" can be used as identifiers.

The header files on OPENSTEP and PDO 4.2 have been sanitized and no longer contain uses of C++ keywords as parameter names, struct field names, or function names. This should make C++ usage easier on OPENSTEP and more similar to other C++ development environments.

Recompiling C++ code with this new compiler may require the either the renaming of certain constructs in C header files you use or the use of extern "Objective-C" instead of extern "C".

Cleanup of predefined symbols (62096)

The macros NEXT_OBJC_RUNTIME and NEXT_PDO are no longer predefined on the Windows NT compiler. You should no longer depend upon them.

Casting a receiver to conform to a protocol is now working (68626).

If, when invoking a method, you cast the receiver to conform to some protocol in order to make sure the compiler invokes the correct method in cases where there is more than one method with the same name, the Objective-C compiler will now pick up on the hint.

Notes From Release 4.1

Including Windows Header Files in Objective-C Code

In general, you should be able to include any Windows header file in an Objective-C source module without issues. The System framework contains Microsoft's header files, with slight modifications to make them compatible with gcc. For instance, slight changes have been made for unnamed unions, Microsoft assembly, and so on. If you have issues including any of the Windows header files, try including the file winnt-pdo.h before the Windows header file that's causing issues.

The -Wmost Compiler Flag

The -Wmost compiler flag is equivalent to FSF's -Wall, except that it doesn't turn on -Wparenthesis. -Wmost also suppresses warning messages about inline functions and static constants that are not actually used. This flag is for internal use andits definition may change in a future release.

Notes From Release 4.0

Frameworks. You can now specify frameworks on the linker and preprocessor command lines. The -framework flag is accepted by both the linker and the preprocessor, while the -F flag is accepted by the linker only. These flags are defined as follows:

-framework framework-name

Search the framework named framework-name when linking. The linker searches a standard set of directories for the framework. It then uses this file as if it had been specified precisely by name. The directories searched by the linker include a couple of standard system directories plus any that you specify with -F.

-F directory

Add the specified directory to the head of the list of directories to be searched for frameworks. If you use more than one -F option, the directories are scanned in left-to-right order; the standard framework directories (LocalLibrary/Frameworks, followed by /NextLibrary/Frameworks) come after.

In your Objective-C code, include framework headers using the following format:

#include <framework/include_file.h>

Where framework is the name of the framework (such as ªAppKitº or ªFoundationº; don't include the extension) and include_file is the name of the file to be included.

If the name of your source file ends in .cc, .cxx, .cpp, or .C, gcc will attempt to compile your program with the C++ compiler. Similarly, if the name of your source file ends in .mm or .M, gcc will attempt to compile your program with the Objective-C++ compiler.

The Objective-C++ compiler is now much more useable than the ones included with OPENSTEP for Windows Prerelease 3 and with PDO 4.0.

Position-Independent Code Generation (PIC). The way the compiler generates code has changed. It now generates position-independent code by default when it builds libraries, bundles and executables. You can control the code generation style using the -dynamic and -static compiler flags; -dynamic specifies that position-independent code generation is to be used, whereas -static specifies position-dependent code generation. For related information, see the note on drivers and kernel servers below.

C++ Templates. The compiler has been updated to support C++ templates or parametrized types. For example, consider the following code:

```
#include <stream.h>
#include <String.h>
#include <SLList.h>
typedef SLList<String> StringList;
main(){
 StringList listOfnames;
```

```
    listOfnames.append("hello world");
    cout <<listOfnames.remove_front() << "\\n";
   }
```

Then the above code is built and run:

```
%> cc++ template.cc -o test -lg++
%> test
hello world
%>
```

Debugging features. The compiler includes a couple new options to assist in debugging. Specify the -H flag on the command to have the compiler emit a listing of included header files (indented to reflect where they are included). Specify the -dM option after the -E (preprocess) option to get a listing of all macros along with their full definitions.

Building drivers and kernel servers. If you are building drivers and kernel servers, be sure to include -static on the command line so that position-dependent code is generated. Compilation with the -dynamic option assumes that the dynamic link editor (/usr/lib/dyld) is present in the running program, and that is not the case for modules to be loaded into the kernel.

Known Bugs and Limitations

The following bugs or limitations are worth noting for the GNU C and C++ Compilers for this release.

Mach programs may need to be recompiled. Since release 4.1 on Mach, libgcc has changed in an incompatible way. It's possible that a small number of existing applications rely on the old libgcc and may crash because of the new libgcc in the base system libraries. We anticipate that this compatibility issue will be resolved in the final version of OPENSTEP 4.2 on Mach; at that time, it may be necessary for you to again recompile anything that now must be recompiled because of this fix.

Inline functions may not be properly expanded. In some circumstances, inline C functions and C++ member functions may not be emitted properly, causing assembler errors. You can work around this issue by ordering your inline function or member-function definitions ahead of their references. Passing -fkeep-inline-functions to the compiler also works around this issue, but may sometimes cause other code-generation issues.

Keyword-switching for extern "Objective-C" may be delayed. Although keyword-switching is no longer done inside a context tagged by the extern "C" linkage directive, the C++ keywords are turned off inside an extern "Objective-C" { ...} range. When entering and exiting this context, the actual switch in keyword sets may occurs a token or two late, meaning that you may get syntax errors on legal code. For example, if the first token following an extern "Objective-C" range is "class", this will be lexed as an identifier and not the C++ class keyword. You can work around this by re-ordering your declarations or inserting a dummy declaration after a keyword-switching boundary.

Link errors on Windows NT (69211). Programs on Windows NT must add explicit references to at least one class in each framework in order to avoid link errors at run time. For instance, you could add a function like that in the following code excerpt, which refers to classes in each of Enterprise Objects Framework's layers. Though never invoked, it forces the appropriate linking to occur.

```
#ifdef WIN32
#import <EOControl/EOControl.h>
#import <EOAccess/EOAccess.h>
#import <EOInterface/EOInterface.h>

void _referenceAllEOFrameworks()
{
       [EODisplayGroup new];       // EOInterface
       [EOEntity new];             // EOAccess
       [EOEditingContext new];     // EOControl
}
#endif
```

If you create your project with the type "EOF Application," this code is automatically added to your project main file.

The -Wno-precomp flag is not supported (63746). The precomp-related options are not yet supported on Windows NT.

Constant strings (both char * and NSString) should be 7-bit only. Unless constant strings are 7-bit, your code will be non-portable as compilers will deal with 8-bit strings in a machine-dependent encoding.

Objective-C++ global constructors. The Objective-C++ compiler sometimes ignores global constructors; they don't always get called.

Random name given to executable by default (66861). If you create an executable and don't use the -o flag to explicitly tell gcc what to name it, gcc will most likely give it a random name.

Using pipes to communicate between compiler passes (61306). The -pipe flag doesn't work in the Windows NT compiler.

Using -pipe (67853). Although the compiler rarely crashes, if it does, it may generate some assembly language output before doing so. If you use the -pipe flag, the assembler may not be able to detect the fact that its input is incomplete. As a result, the assembler may produce an incomplete, but valid .o file. If you use the make utility to build your application, make will detect the fact that there was an issue during compilation. However, when make is subsequently invoked, it might not recompile the source file that caused the issue, and the linker will most likely complain about unresolved external symbols.

ObjC++ requires -lstdc++ when using C++ streams on PDO (69156). When compiling C++ programs that use C++ streams with gcc on PDO platforms, if you specify the -ObjC++ flag you must also specify the -lstdc++ flag. So, for example, a program "foo" that uses cout (and therefore includes iostream.h) would be compiled using gcc as follows:

gcc -ObjC++ foo.cc -lstdc++

__declspec(dllexport) __stdcall doesn't work (69194). On Windows NT, functions that are declared as __declspec(dllexport)__stdcall aren't handled properly. This may affect some Windows header files that you include in your programs.

The compiler sometimes tries to create a library instead of an executable (69087). This happens on Windows NT when a function is declared as __declspec(dllimport) (perhaps in a header file), but the function is actually defined in the file being compiled. The workaround is to remove the offending __declspec(dllimport).

Inconsistent function declarations involving stdcall produce unexpected results (69506). On Windows NT, if a function is forward-declared to be stdcall but not declared to be stdcall in the actual function definition, the compiler will emit code to pop the arguments off the stack, but won't adjust the function name.

The linker complains about objects exported as CONSTANT (70212). On Windows NT, if you're building a framework and you create your own DEF file for it, defining exported objects as CONSTANT will produce a warning from the linker advising you to use the word DATA instead. If you substitute the word DATA for CONSTANT in your DEF file, some or all of your objects won't be exported correctly; the linker will be unable to find them. As a workaround, simply leave the declarations CONSTANT and ignore the linker warnings.

-static option causes linking to fail (70326). The -static and -dynamic compiler flags are meaningless on Windows NT, and shouldn't be used.

Static constructors can't be used for run-time class initialization (54831). The PDO compiler can't apply a user-defined constructor to a global or static C++ object and send an Objective-C message in the same file. To work around this issue, eliminate the constructor, the global, or the Objective-C code.

wchar_t string literals (38759). The compiler generates wide-character literals for the host endian-ness only. For example, if you are cross-compiling the string L"x" from m68k to i386, it will be a big endian wide string. The only workaround is not to cross-compile modules which depend on wide characters.

Compiler Tools

This file contains release notes for the 4.2 release of the Compiler Tools. It contains information about the following topics:

- The NeXT Mach-O GNU-based assemblers
- The NeXT Mach-O static link editor
- The NeXT Mach-O dynamic link editor
- Mach-O object tools (nm, otool, and so on)

Notes Specific to Release 4.2

New Features

There are no new features for the 4.2 release of the compiler tools.

Notes Specific to Release 4.1

New Features

There is only one new feature for the 4.1 release: The dynamic linker now has the environment variable DYLD_FRAMEWORK_PATH to better support the development of frameworks. See the man page for details.

Notes Specific to Release 4.0

New Features

Dynamically Linked Shared Libraries

The compiler tools now allow you to build and develop dynamic shared libraries and support the programs that use these libraries, including programs that use bundles. The tools to build or use dynamic shared libraries are in the 4.1 updates for the m68k, i386, sparc, and hppa target architectures.

All object files that are part of a dynamic shared library or that are to be in an executable should be compiled with the -dynamic flag. The -dynamic flag is now the default. Executables using shared libraries must also be linked with this flag when using cc(1) or ld(1) and must be using crt1.o (this is done automatically with cc(1) and the -dynamic flag). To build a dynamic shared library, use libtool(1) with the -dynamic option; typically you also specify the -install_name library_name option as well as other options (see the libtool(1) man page).

The dynamic linker is becoming more fully-featured. It contains some programmatic support for runtime loading (but as of yet no unloading or replacing).

The static link editor uses the symbol tables of dynamically-linked shared libraries to cause modules for undefined symbols to be pulled in from static libraries and to check for undefined symbols. The ld(1) flags for undefined checking -undefined {error, warning, suppress} can be used; the default is to treat undefined symbols as errors. This default holds for dynamically-linked shared libraries and bundles. In these cases the dependent libraries should be listed if available. If not available then -U _symbol or -undefined {warning, suppress} can be used until they are.

Using and Building Dynamic Shared Libraries from Project Builder

The 4.1 version of Project Builder supports a library project type which by default is a dynamic shared library and a framework project type which by default contains a dynamic shared library. Project Builder supports the use of dynamic libraries in other project types. To build static libraries, un-comment the LIBRARY_STYLE definition in the project makefile (LIBRARY_STYLE is set to STATIC and commented out).

Tools that are complete

The assember, link editor, and otool support position-independent code for the m68k, i386, sparc, and hppa architectures. The link editor, assember and otool fully support indirect undefined references using symbol pointers and symbol stubs. And the assembler now fully supports Mach-O files.

The dynamic link editor now has the first level of support for runtime loading. Currently only loading of MH_BUNDLE files is supported. Comments in the header file /NextDeveloper/Headers/mach-o/dyld.h describe what is not yet implemented.

Tools that are not complete

The dynamic link editor now has the first level of support for runtime loading. Currently only loading of MH_BUNDLE files is supported. Comments in the header file /NextDeveloper/Headers/mach-o/dyld.h describe what is not yet implemented

The tool segedit(1) does not have support for dynamic shared libraries.

The NeXT Mach-O GNU-based Assemblers

The NeXT assembler now a fully supports Mach-O files with the ability to create arbitrary sections with the .section and .zerofill directives. Contents of sections now correctly reflect the assembly code with respect to the section aligment and no unnecessary padding is added.

Major New Features

Support for position-independent code through the use of a new relocatable form of an expression: "add_symbol - subtract_symbol + offset" where add_symbol and subtract_symbol can be defined in different sections.

Documentation

Assembler Manual

The assembler manual has been updated to reflect support for dynamically-linked shared libraries. It contains appendices of the instructions for the i386, M68K, and PA-RISC processor architectures. An RTF version of the Assembler manual is in: /NextLibrary/Documentation/NextDev/Reference/DevTools/Assembler

Converting Your Code to OPENSTEP

This document describes how to convert your code from NEXTSTEP Release 3.x to OPENSTEP for Mach Release 4.x.

Release 4.0 is NeXT's first OpenStep-compliant release. OpenStep is an API that enables platform-independent development of client/server applications. The OpenStep API includes the Application Kit, the DPSClient library, and a new kit called the Foundation Framework, which provides an operating system independence layer. The OpenStep Application Kit is functionally equivalent to the NEXTSTEP Release 3 Application Kit, but its API has been reworked to make use of the Foundation Framework. Because Release 4.0 is OpenStep compliant, converting your code to it is a good way to make your application an OpenStep application.

To convert your code, you run a series of scripts. These scripts use tops, a tool that performs in-place substitutions on source files according to a set of rules. The script files contain the rules that tops applies to your code. Most of the scripts are provided in the release, but you must generate some of them before you start converting because they work directly on the custom classes in your code. OPENSTEP for Mach provides a tool that allows you to generate these scripts.

The scripts convert most of the NEXTSTEP API to the new OpenStep API. Some methods, classes, and functions have been altered in such a way that an automated conversion is not possible. For these, the conversion scripts produce an error message that identifies the obsolete code and tells you how to convert it.

You run the conversion in six stages. Each stage runs a different set of scripts. After each stage, you compile your code to identify places where the conversion was not automatic. It is recommended that you run some additional scripts to replace the Common classes with OpenStep API, making your code even more portable.

This document tells you how to set up your project for conversion and how to run the conversion scripts. A separate document, the OpenStep Conversion Guide, describes the changes made during each of the conversion stages and the reason for those changes. Its location on-line is /NextLibrary/Documentation/NextDev/Conversion/ConversionGuide. Read the first chapter of this guide (00_Intro.rtfd) for an overview of the differences between NEXTSTEP 3.X and OpenStep and for a discussion of the different strategies you might use when converting.

The Conversion Process

To convert your code, do the following:

1. Convert your project to a 4.0 project.

2. Generate the conversion scripts.

3. Run the six-stage conversion process and any optional conversions.

4. Convert your nib files.

5. Debug your application.

These steps are described further below.

Converting Your Project to a 4.x Project

Before you start the conversion process, you need to change your project and makefiles so that they use the new Release 4.0 development environment. The 4.0 development environment has many significant improvements over the 3.3 development environment. In particular, Project Builder has changed significantly. To convert your project, perform the following steps:

1. Read OPENSTEP Development: Tools and Techniques and the release notes for Project Builder and Interface Builder to learn about changes to the environment.

The document you are reading now does not describe how to use the new Project Builder. The book OPENSTEP Development: Tools and Techniques is on-line in the directory /NextLibrary/Documentation/NextDev/TasksAndConcepts/DevGuide. The release notes are in the directory /NextLibrary/Documentation/NextDev/ReleaseNotes.

2. Make sure your code compiles cleanly without warnings.

Perform this step so that any warnings that show up during conversion won't become mixed in with pre-existing warnings. Make sure the -Wall compiler option is being used.

Before you compile your 3.3 code on a 4.0 system, you need to change the search path for header files to the directory /NextDeveloper/OpenStepConversion/3.3Headers. To do this in the new Project Builder:

1. Choose Inspector from the Tools menu to bring up the project inspector.

2. From the inspector pop-up list, choose Build Attributes.

3. Choose Header Search Order from the pop-up list in the Build Attributes inspector.

4. Type /NextDeveloper/OpenStepConversion/3.3Headers and click Add.

3. Back up your project directory.

The conversion scripts modify your code in-place, and they do not create backups for you. It is strongly recommended that you back up your project after each conversion stage in addition to backing up before you begin, provided you have enough space.

4. Delete the NeXT-provided libraries (such as libNext) from your project, and add the corresponding frameworks (such as /NextLibrary/Frameworks/AppKit.framework).

All NeXT-provided libraries are replaced with frameworks in 4.0. A frameworks' executable code is a dynamic shared library. To add the Application Kit framework, in Project Builder choose Add File from the Project menu, select /NextLibrary/Frameworks/AppKit.framework from the Add File panel, and choose Frameworks from the file type pop-up list on the Add File panel. Add the Foundation Framework in the same way.

Frameworks are bundled differently than shared libraries. All of the support files for a framework are contained in the same directory, so you no longer have to know that the library itself resides in one place, its header files another place, and its documentation still a third place.

When you add a framework to your project, it doesn't appear in the Libraries suitcase. Instead, it appears in the Frameworks suitcase. You are able to see that framework's header files and documentation underneath that suitcase.

5. Change the application class in Project Builder.

In OpenStep, all keywords are prefixed with "NS", so the Application class is now NSApplication. If you are converting an application project, you need to change the class in Project Builder so that it will use the appropriate class when updating your main function. To do this, bring up the project inspector by choosing Inspector from the Tools menu. In the inspector, choose Project Attributes. Finally, type NSApplication in the field labelled Application Class.

6. Convert your makefiles.

The new Project Builder comes with new Makefile.postamble and Makefile.preamble files. Convert your preamble and postamble files if you performed some customization on them. You can find copies of the new templates in the directory /NextDeveloper/Makefiles/project. Rename your existing preamble and postamble files, copy the new templates into your project directory, rename the template (remove the .template extension), and merge any customizations you would like to keep into the new templates.

Most of the changes to the makefiles are additions made to support frameworks, however some makefile variables are now obsolete. The additions are documented in the comments in the preamble and postamble files. The following table lists the obsolete makefile variables and what you should use as a replacement.

Obsolete Makefile Variable Possible Replacement

BUNDLELDFLAGS OTHER_LDFLAGS

PALLETTELDFLAGS OTHER_LDFLAGS

COMMON_CFLAGS OPTIMIZATION_CFLAG, WARNING_CFLAGS

NORMAL_CFLAGS OPTIMIZATION_CFLAG, WARNING_CFLAGS

DEBUG_CFLAGS Use DEBUG_BUILD_CFLAGS.

PROFILE_CFLAGS Use PROFILE_BUILD_CFLAGS.

DYLD_APP_STRIP_OPTS LIBRARY_STRIP_OPTS (-S by default)

RELOCATABLE_STRIP_OPTS DYNAMIC_STRIP_OPTS (-S by default)

OTHER_DEBUG_LIBS Add libraries using Project Builder.

OTHER_PROFILE_LIBS Add libraries using Project Builder.

OTHER_JAPANESE_DEBUG_LIB Add libraries using Project Builder.

OTHER_JAPANESE_PROFILE_LIBS Add libraries using Project Builder.

BUNDLE_LIBS Add libraries using Project Builder.

PRECOMPS Use Project Builder Inspector to mark headers for precompiling.

In addition, the following are some other changes to makefiles of which you should be aware:

- If your project is a library shared by several other projects, consider converting it to a framework. For more information, see the book OPENSTEP Development: Tools and Techniques.
- Many things that you used to have to set using the Makefile preamble and postamble files you can now set using Project Builder. For example, you can set search paths and simple compiler flags. You should minimize your use of the preamble and postamble files and use the Project Builder interface instead. For more information, see the development environment release notes.
- The build process now uses gnumake instead of make.
- If you wrote any top-level double-colon targets that are also implemented by Project Builder, such as app::, install::, all::, now is a good time to rename them. It is likely that the variables passed to these rules and the order in which they are executed has changed. Consider using after_install::, before_install::, OTHER_INITIAL_TARGETS, or OTHER_PRODUCT_DEPENDS.
- Once you save your project in 4.0, it uses the new makefile behavior. If your project must use the 3.3 makefile behavior, set MAKEFILEDIR in Makefile.preamble to /NextDeveloper/Makefiles/app.

Generating the Conversion Scripts

Some of the conversion scripts need to understand your application's class hierarchy and how you implemented certain methods. For this reason, you must generate some of the conversion scripts yourself.

To generate conversion scripts, do the following:

1. Add /NextDeveloper/OpenStepConversion/UtilityScripts/shellscripts to your PATH environment variable. The convert command, which you use to convert your code, is in this directory.

2. In a Terminal window, enter these commands to create files that will be used to generate the conversion scripts:

% cd project_directory

% convert -preprocess

3. Modify the files StringMethods, StringDefines, RectMethods, and VoidMethods, which are used to generate the conversion scripts. Carefully read "Modifying the Files Used to Generate Conversion Scripts" below for instructions on how to do this. Once you perform step 4, you cannot return to this step.

WARNING: Do not move on to step 4 until you have fully completed step 3.

4. Generate the optional conversion scripts with this command:

% convert -makescripts

Modifying the Files Used to Generate Conversion Scripts

The convert -preprocess command creates a CONVERSION directory under your project directory and stores in it files that describe your application. These files and their contents are described in the table below.

File Description

ClassHierarchy1 Describes the class hierarchy before conversion in a format tops can understand.

ClassHierarchy2 Describes the class hierarchy after conversion in a format tops can understand.

StringMethods Lists methods that have (char *) or (const char *) as either a parameter type or return type.

StringDefines Lists #defines that were determined to be of type (const char *).

RectMethods Lists methods that use pointers to NXRects, NXSizes, or NXPoints as either a parameter or a return type.

VoidMethods Lists methods that did not specify a return type.

In order to generate conversion scripts that will convert your code properly, you need to modify all of the files produced by convert -preprocess except the class hierarchy files. The following sections provide instructions on this step.

After you modify these files and run convert -makescripts, some additional conversion scripts appear in the CONVERSION directory. These scripts are executed during the conversion process.

StringMethods

OpenStep provides a new object called NSString. NSString allows you to perform character manipulation on strings without requiring that you know which character encoding is being used. Using NSStrings, you can write truly portable and internationalized code, code that will work with any writing system supported by the Unicode standard. The Application Kit now uses NSStrings where it used to use C strings in method and function arguments and return values. Because of this and because of the advantages of NSStrings, you may want to convert all of the C strings in your application so that they use NSStrings.

The StringMethods file contains a list of every method in your application that takes a C string as an argument or returns a C string. It does not list overrides of Application Kit methods; those are taken care of by the conversion scripts provided in the release. All of the methods listed in this file will have their C string arguments and return values converted to NSStrings.

Only methods that don't modify the string should have their C strings converted. Look at the implementation of every method listed in the StringMethods file. If the method modifies its C strings, remove its name from the file. To skip the optional conversion of C strings to NSStrings entirely, delete all of the methods from this file. (You may want to save them in a different file.) Before you decide, you may want to read about the conversion of C strings to NSStrings in the OpenStep Conversion Guide. See the chapter "Converting the Common Classes."

You can locate a method's implementation easily in Project Builder by doing the following (for more information, see the development environment release notes):

1. Choose Find from the Tools menu to display the Project Find panel.

2. In the Project Find panel, enter the name of the method in the text field.

3. Make sure Definition is selected in the pop-up list.

4. Click the Find button.

StringDefines

This StringDefines file contains #define macros that are string constants or NXLocalizedString... function calls. These macros will be converted so that they create NSString objects instead of C strings. If this file lists macros that you want to remain C strings, delete the line naming that macro from the StringDefines file.

RectMethods

All Application Kit functions and methods that used to take the address of an NXRect or an NXSize now take the value of the structure. Similarly, all Application Kit functions and methods that used to return a pointer to an NXRect or NXSize now return the structure itself. This change was made to eliminate the aliasing issues that can occur when you pass pointers and to allow these methods to work better with the Distributed Objects system.

The RectMethods file contains a list of every one of your application's methods that takes a pointer to an NXRect, NXSize, or NXPoint structure or returns a pointer to one of these structures. (It does not list overrides of Application Kit methods.) All of the methods listed in this file will have their structure pointer arguments and return values converted to the actual structure.

Only methods that don't modify the structures should have their arguments and return types modified. Look at the implementation of every method listed in the RectMethods file. If the method modifies an NXRect, NXPoint, or NXSize structure, remove its name from the file. To skip the optional conversion of structure pointers entirely, delete all of the methods from this file. (You may want to save them in a different file.) Before you decide, you may want to read about the NXRect, NXPoint, and NXSize conversions in the OpenStep Conversion Guide. See the chapter "Converting the Common Classes."

VoidMethods

Previously, methods returned self by convention. Some methods return self to indicate success and nil to indicate failure. Returning self to indicate a Boolean value or returning self without any associated meaning made the API more confusing. In OpenStep, when a method has no real value to return, its return type is void. Where a method returned self or nil, it now returns BOOL. In addition to being cleaner API, returning void and BOOL helps you avoid creating unnecessary proxies if you're distributing objects. The VoidMethods file contains a list of every method in your application that has no return type specified (except for overrides of Application Kit methods).

Look at both the implementation and the uses of each of the methods listed in the VoidMethods file and perform the action listed below. (To look at all of the uses of a method, enter its name in Project Builder's Project Find panel, choose References from the pop-up list, and click Find. The bottom half of the Find panel lists all of the places the method is invoked.)

- If the method returns either self or nil and invocations of the method test the return value, change the prefix for that method in the VoidMethods file to SELFNIL-BOOL. This will convert the method to return BOOL. (By default, all methods in the file are prefixed with SELF-VOID, which means they will be converted to return void.)
- Delete the method from the VoidMethods file if its return type is ever used in any of the places where it is invoked (and it should not be converted to return BOOL).
- init... methods do not appear in the VoidMethods file because it is correct for them to return type id. If you have a method that starts with init... but is not a initialization method for its class, add it to the VoidMethods file if it should return void.
- Leave all +initialize methods in the file. The +initialize method now returns void.
- If the method returns a value other than self and that value is never used anywhere the method is invoked, change its prefix to OBJ-VOID.
- To skip the optional void conversion, delete all of the methods from the VoidMethods file. (You may want to save them to a different file.)

For example, consider the methods shown in the following code fragment. All of these methods except newCount would be listed in the VoidMethods file because they don't specify a return type. However, the countingObject method has a meaningful return value because countSomething expects it to return an object. countSomething is is the only method that should truly be converted to return void because it is invoked as if it already did return void. Thus, in the VoidMethods file, you would delete countingObject but leave countSomething.

```
- countingObject
{
return countingObject;
}

- countSomething
{
[[self countingObject] incrementCount];
return self;
}

- (int)newCount
{
[self countSomething];
return [countingObject currentCount];
}
```

Before you decide which methods should be converted to return void, you may want to read about the void conversion in the OpenStep Conversion Guide. See the chapter titled "Global API and Style Changes."

Running the Conversions

The conversion process is organized into six stages. Each stage runs a series of scripts on your code and makes changes based on the information in those scripts. When converting code for the first time, you should perform the conversion in stages. Here's the recommended procedure:

1. Back up the project directory.

2. In Project Builder, close all of the source files.

The convert script, which you run in the next step, changes your source files. If you have looked at these same source files in Project Builder before you run the script, the file displayed by Project Builder won't reflect the changes that convert makes. To make sure that you are always looking at the latest version of your files, close all of the files in Project Builder before you run the script.

You can see which files you have loaded in Project Builder using the Loaded Files panel. Choose Loaded Files from the Tools menu to bring up the Loaded Files panel. Select a file in the Loaded Files panel, then choose Close from the File menu to close it.

If you don't perform this step, convert will still work properly, but when you look at the source files after it is complete, they won't reflect the changes. To see the changes that convert made, press Command-u.

3. In a Terminal window, enter:

% cd project_directory

% convert -stagex

where x is the number (1 through 6) of the conversion stage you want to perform. If you don't specify source files on the command line, they will be identified with the pattern:

*.[hcmCM] *.psw* *.*proj/*.[hcmCM] *.*proj/*.psw*

In other words, all code files in your current directory and in the first level of subproject directories will be converted. If this is not sufficient, specify the appropriate file list after the -stage option:

convert -stagex file1 file2 ...

Each conversion stage takes several minutes to complete. Stage 1 is the longest stage.

WARNING: The conversion scripts should not be run out of order, and it is not recommended that they be run on the same file more than once. In general, it's a good idea to save a copy of your files after each stage.

4. Once the conversion is complete, use FileMerge to compare your project with the backup of your project. This is a good way to learn about the differences between NEXTSTEP and OpenStep. (To learn how to use FileMerge, see the development environment release notes.)

5. Open the project in Project Builder and use the Inspector panel to add /NextDeveloper/OpenStepConversion/IntermediateFrameworksx to the search path for frameworks, where x is the number of the conversion stage. (For stages 2 through 6, remove the IntermediateFrameworks directory for the previous step.)

In Project Builder, you change the search paths for frameworks from the Build Options inspector. Choose Inspector from the Tools menu to bring up the inspector panel, and choose Build Options from the inspector's pop-up list. In the Build Options inspector, there is another pop-up list. Choose Framework Search Order from that list. Type the new search path for frameworks, then click Add.

In between the first conversion stage and the last conversion stage, your code is in an interim state and will not compile successfully with either the NEXTSTEP 3.X headers or the OPENSTEP for MachOS Release 4.0 headers. The IntermediateFrameworks directories have NEXTSTEP headers at the intermediate stages of conversion so that your code will compile. Your code will not link successfully until after the sixth stage.

There is no IntermediateFrameworks directory for stage 6. After stage 6, you should use the default search path for frameworks (/NextLibrary/Frameworks).

NOTE: Be sure you change the Framework Search Order, not the Header Search Order.

7. Build your project and work through any error messages.

The conversion process places #error messages in places where automated conversion was not possible and #warning messages in places where the conversion might not be correct. You will see these messages when you compile. Once your code compiles successfully, back up your project again, and run the next stage.

If you need help deciding how to correct an error, see the OpenStep Conversion Guide. It describes how to correct most of the errors that occur. If you need more information about a particular class or function, look in the Foundation Framework Reference in /NextLibrary/Frameworks/Foundation.framework/Resources/English.lproj/Documentation or the Application Kit Reference in /NextLibrary/Frameworks/Foundation.framework/Resources/English.lproj/Documentation. If the class has no documentation yet, see the OpenStep Specification in /NextLibrary/Documentation/OpenStepSpec.

NOTE: If Project Builder is not showing you the updated source files (the source code does not match the warning you see), type Command-u. Be sure to close all files in Project Builder as described in Step 3 before you run the next conversion stage.

You may want to set the Continue After Error preference to Project Builder. If you do, Project Builder will continue to build even after it finds an error. You can find the Continue After Error preference in the Preferences panel, under Build.

8. If you're converting an application project, convert your nib files. To do this, use this command:

% convert -nib

Running All Conversions At Once

After you have converted at least one project and you are more familiar with the conversion, you may want to run all conversions at once. To do this, enter this command in the terminal window:

convert -all

This command runs all six conversion stages one by one, then converts any nib files. Before you enter this command, you still must generate the conversion scripts for the project as described earlier in this document. Remember to be very careful when modifying the files used to generate the conversion scripts. It will save you time in the end.

Running the Optional Conversions

After you have completed all of the conversion stages you may wish to run remaining optional conversions. The optional conversions are listed below.

Conversion Script Purposes

CustomIBAPI.tops Converts Interface Builder API for palettes.

ListToMutableArray.tops Converts List objects.

HashAndStringTableConversion.tops Converts HashTable and NXStringTable objects.

StringConversion2.tops Converts more C strings to NSStrings.

StreamToMutableData.tops Converts streams to NSMutableData objects.

StreamToString.tops Converts streams to NSString objects.

TableView.tops Converts NXTableView objects to NSTableView objects.

VMConversion.tops Converts MachOS virtual memory functions to Foundation functions.

To run a single script on your source code, use this command:

tops -scriptfile scriptFile *.[hcmCM] *.psw* *.*proj/*.[hcmCM] *.*proj/*.psw*

Where scriptFile is the complete path for the script (/NextDeveloper/OpenStepConversion/ConversionScripts/scriptName). See the OpenStep Conversion Guide for information on these scripts.

NOTE: Because the API changes between C strings and NSStrings and between NXTableViews and NSTableViews are significant, the usefulness of the scripts StringConversion2.tops and TableView.tops vary. You may want to run them on a copy of your code first to see if they help you.

The GNU Source-Level Debugger

This file contains information about GDB, the GNU Debugger. For more information, see the debugging chapter in the OPENSTEP Development Tools Reference manual. On Mach, you may also refer to the gdb(1) manual page.

Notes Specific to GDB on Mach:

New GDB Version

The GDB debugger in OpenStep 4.0 for Mach (and later versions) is based on the version 4.14 release from GNU/FSF. This brings with it many bug fixes and new features, many of which are mentioned in the debugging chapter of the OPENSTEP Development Tools Reference manual.

New Features

Dynamic Link-Editor Support

GDB supports debugging of dynamic shared libraries (sometimes known as Frameworks or Bundles in the OPENSTEP world). The presence of dynamic shared libraries has some impact on debugging, which is described in this section.

Debugging symbols for dynamic shared libraries are not present in the program itself. GDB obtains them when the running program attaches and links to the shared library. This means that before the program is actually running, GDB has no information about the contents of the dynamic shared libraries that it uses.

Because of this, it is not possible to set ordinary breakpoints in a shared library before that library has been attached. GDB provides a new command for this purpose, future-break or fb. If GDB cannot find the necessary symbols to resolve a future-break command, it defers the breakpoint and attempts to resolve it later, when new symbols from a shared library become available. Caveat: since the future-break command deals with names and symbols that are as yet unknown to the debugger, it cannot check spelling for you; if you make a spelling mistake, it will never be detected and the breakpoint will never take effect.

There is also an environment variable, DYLD_LIBRARY_PATH, which tells the dynamic link-editor where to search for dynamic libraries. This variable can be used to cause a library with debugging symbols to be linked, even though the library on the default path has no symbols. This environment can be set from within GDB by using the setenv command. In order to affect the program being debugged, it should be set before running the program.

The "view" interface

In prior releases, GDB supported a GUI interface that used the NEXTSTEP Edit application as a source file viewer (invoked by the view command). Edit has been replaced by Project Builder as the source file viewer for GDB, and the view command now connects GDB to Project Builder. You must start Project Builder yourself before giving GDB the view command (GDB will not start Project Builder automatically). Project Builder has its own user interface for interacting with GDB (see the Project Builder documentation).

Methods with Variable Number of Arguments

GDB now understands the syntax for calling a method with a variable number of arguments (for example, [MyClass myMethod: 1, 2, 3, 4]).

Known Issues

Debugging Apps that Use the Sybase Client Library

GDB hangs (actually, the new Sybase CT-Lib adaptor blocks) when you use the next command to step over a line of code which eventually causes a call to the Sybase client library.

More generally, when debugging a program that uses multiple threads it's possible to create a situation in which a deadlock will occur. Whenever the next or step commands are issued, GDB lets only the thread being debugged to execute. All other threads are suspended until the command is completed. Therefore, if you attempt to step over a line of code which tries to communicate with another thread, the program will deadlock.

To deal with issues like this, a "run-all-threads" option has been added to GDB. This controls whether or not all of the threads should execute while single-stepping. The default value for this option is "off", meaning the behavior is the same as in OPENSTEP 4.1. In order to prevent a deadlock like that described above, issue the following command in GDB:

set run-all-threads on

We recommend that you use this option only if you're experiencing a deadlock. Allowing other threads to execute while stepping through code can produce confusing results if, for example, the other threads may be changing the values of global data.

Known Issues with Dynamic Link-Editor Support

It has been observed that GDB sometimes hangs or crashes if you run a program that uses a dynamic shared library (Framework or Bundle), then recompile the dynamic shared library, and run the program again. If this happens to you, we recommend that you quit GDB and start a new debugging session every time you rebuild the library. You can use the .gdbinit file to help re-establish things such as breakpoints that you need in your debugging session.

Interrupting with ^C during Dynamic Symbol Loading

Immediately after you start your program running under GDB, the program will start to load dynamic shared libraries, and GDB will begin reading symbols from these libraries. If you attempt to interrupt GDB by typing ^C (control-C) during this process, the debugger will be left in a confused internal state from which the only known recovery is to quit the debugger and start over.

Notes Specific to GDB on Windows:

GDB Version

The GDB debugger for OPENSTEP for Windows is based on the version 4.15.1 release from GNU. This brings with it many, if not most of the features of debugging on UNIX and Mach, although there are inevitably some differences.

New Features

Dynamically Loaded Library (DLL) Support

GDB supports debugging of dynamically loaded libraries (DLLs). In OPENSTEP for Windows, Frameworks and Bundles are implemented as DLL's. The presence of DLLs has some impact on debugging, which is described in this section.

Debugging symbols for dynamically-loaded libraries are not present in the program itself. GDB obtains them when the running program attaches and links to the DLL. This means that before the program is actually running, GDB has no information about the contents of the DLLs that the program uses.

Because of this, it's not possible to set breakpoints or access data in a DLL before the DLL has been attached by the program. GDB provides a new command for this purpose, future-break or fb. If GDB cannot find the necessary symbols to resolve a future-break command, it defers the breakpoint and attempts to resolve it later, when new symbols from a shared library become available. Caveat: since the future-break command deals with names and symbols that are as yet unknown to the debugger, it cannot check spelling for you; if you make a spelling mistake, it will never be detected and the breakpoint will never take effect.

Attach and Detach

GDB's attach command works pretty much as it does on Mach. The process ID to attach to can be obtained from PVIEW, or by having the attachee call getpid() and output the result. However, when GDB attaches to an already-running process, it won't learn about symbols from DLLs that the process has already linked to.

The detach command is only partially useful at this time. detach will let the attached process continue to run, but a parent/child relationship continues to exist between the debugger and the detached process. Because of this, if you then quit the debugger, the detached process will also die.

When you attach to a running process, you will frequently find yourself in a non-debuggable area of code from which you cannot even get a backtrace. See the section on known issues, "Non-Debuggable Code" below for more information on this topic.

Add-Symbol-File

When GDB attaches to a running process, it does not read any symbols from DLLs that the process has previously linked itself to. If you need

those symbols for debugging, you can explicitly cause GDB to load them by using the add-symbol-file command. This command takes two arguments: the fully-qualified filename of the DLL file, and a base address. For a DLL that you build, this base address will usually be the base address at which you linked the DLL plus 0x1000. However, if the address of a DLL that you build conflicts with another DLL in the process, it may automatically be assigned a new address. If you run the program under GDB (instead of attaching to it), GDB displays the address at which each DLL actually landed.

Here are the base addresses to give to the add-symbol-file command for the major OPENSTEP DLLs:

· 0x30001000 System

· 0x31001000 nextpdo

· 0x32011000 Foundation

· 0x34021000 AppKit

· 0x38031000 NeXTApps

· 0x3A041000 DevKit

· 0x3C051000 ProjectBuilder

· 0x3C051000 InterfaceBuilder

· 0x40001000 Message

· 0x42011000 WebObjects

· 0x44021000 EOControl

· 0x46031000 EOAccess

· 0x48041000 EOInterface

· 0x4A051000 Sybase

· 0x4C061000 Oracle

· 0x4E071000 Informix

· 0x50081000 nextorb

· 0x52091000 EOModeler

Command Editing

GDB's command line history can be accessed by using the up and down arrow keys, or by using the EMACS key bindings (^P and ^N to scroll thru previous commands, ^B, ^A, ^E to move around on a line, and so on). Also, set history expansion on enables C-shell-like command history within GDB (!!, !print and so on). As usual, an empty newline repeats the previous command (except where specifically disabled, as with the run command).

Debugging Objective-C: Differences from Mach GDB

The Windows version of GDB has separate features for many different languages, including Objective-C. It attempts to guess the source language by looking at the extension of the source file name (".m" or ".M" for Objective-C). By default, GDB's ªcurrent languageº is Objective-C. At any time, you can find out what GDB's ªcurrent languageº is with show language. To force the current language to Objective-C, type set language objective-c.

Calling Methods from GDB

To call a method in your program from GDB, use the print, set, or call commands with an argument that looks just like a method call in Objective C, as shown here:

(gdb) print [myClass showValue: 12]

If the method comes from a Category, you must include the category name, like this:

(gdb) print [myClass(myCategory) showValue: 12]

Listing and Setting Breakpoints on Methods

To refer to a method in a list or break command, you can give the full class and method name, including a `+' or `-' to indicate a class method or instance method. If there is a category name, you must give that too:

(gdb) list +[myClass init]

(gdb) break -[myClass(myCategory) showValue]

You can also set breakpoints or list a method just by giving a selector. If the selector is implemented by more than one class, gdb will list the corresponding methods and ask you to choose one or more:

(gdb) break init

[0] cancel

[1] all

[2] -[Change init] at Change.m:20

[3] -[DrawApp init] at DrawApp.m:130

[4] -[Graphic init] at Graphic.m:139

>

You would then enter your choice or choices at the ">" prompt.

Getting Information about Classes and Methods

GDB for Windows now has the info classes and info selectors commands. These commands accept the same regular expression language as GDB's info type and info function commands (ie. the Unix style regular expression language). This is a change from the Mach gdb, where info classes and info selectors accept a slightly different regular expression language. For instance, to learn about class names beginning with NS (using the '^' character to designate ªbeginning withº):

(gdb) info classes ^NS

To learn about selectors, you can use the info selectors command. To find every selector containing the string "withObject:" you could enter:

(gdb) info selector withObject:

To learn about methods, you can use the info function command, which also takes a regular expression. Since the square bracket characters `[' and `]' are significant in regular expressions, you can quote them with a backward slash to prevent their being treated as special characters. To list all the methods of a class, you might say:

(gdb) info function \\[MyClass

To list all the methods whose selector ends with ªcount:º, you might say:

(gdb) info function count:\\]

If you want to know about a specific method of a specific class, but you are not sure if it belongs to a category, you could use the ª.*º wildcard sequence to stand for ªany number of any charactersº:

(gdb) info function MyClass.*mySelector:

Debugging Threads on Windows

The GDB for Windows is thread-aware. If you are debugging a multi-threaded program, you can use the info threads command to see a list of the

currently active threads. Use the thread command to switch to one of the threads listed by info threads, giving it the number of the thread you want to debug (a small integer such as 1 or 2, not the thread ID).

When you switch threads, you will frequently find yourself in a non-debuggable area of code from which you cannot even get a backtrace. See the section on known issues, ªNon-Debuggable Codeº below.

Known Issues

Non-Debuggable Code

When you interrupt a program with ^C, attach to a running program, or switch threads in a running program, in very rare instances the program will be in the middle of executing Windows code that cannot be debugged. Occasionally you'll find that GDB cannot even give you a backtrace, because Windows has done something with the program stack. When this happens, if you don't want to simply let the program continue (for instance, you need to know exactly how you got to where you are), you can use the stepi command to step by single machine instructions until the Windows code cleans up the stack and returns, at which time you will suddenly be able to see symbols and backtraces again. GDB will notify you when you have returned to a symbolic region (say, a function or a method) that it knows about. Usually this does not take too long; on the order of a few dozen instruction steps.

Documentation

This file contains release notes for the Documentation distributed with this release of OPENSTEP 4.2.

Locating the Developer Documentation

All of the documentation for OPENSTEP 4.2 can be found on-line (some of the documents are supplied in printed form, as well). On OPENSTEP for Mach, the easiest way to access this documentation is to open the NextDeveloper bookshelf using Digital Librarian (this bookshelf can be found in /NextLibrary/Bookshelves). Although the NextDeveloper bookshelf can be used directly to access the documentation, most developers prefer to create their own custom bookshelf containing just those documents of interest. Select the first entry in the NextDeveloper bookshelf, then click ªList Titlesº; the documents that are then listed detail how to create your own custom bookshelf.

In NEXTSTEP Release 3.3, as well as in prior releases, all developer documentation was located in a subdirectory of /NextDeveloper/Documentation/NextDev. In OPENSTEP 4.2, framework documentation has been moved to a location inside of the relevant framework. All remaining developer documentation can still be found under /NextDeveloper/Documentation/NextDev.

Driver Development

OPENSTEP 4.2 cannot be used to develop Mach device drivers. Because NEXTSTEP 3.3 device drivers work on OPENSTEP 4.2 systems, we recommend that you use NEXTSTEP 3.3 Developer to create device drivers.

In keeping with the philosophy that all framework resources be located within the framework, framework reference documents are located in the directory Resources/English.lproj/Documentation, relative to the ª.frameworkº directory. So, for instance, reference documentation for the Application Kit Framework can be found in /NextLibrary/Frameworks/AppKit.framework/Resources/

English.lproj/Documentation.

OPENSTEP Enterprise

On OPENSTEP Enterprise, double-click the BooksOnline entry in the NeXT Software program group to gain access to the complete on-line documentation set.

PDO

On PDO platforms, all documentation is located in /NextLibrary/Documentation.

Release Notes

/NextLibrary/Documentation/NextDev/ReleaseNotes contains important information about the release that was known at the time that the OPENSTEP 4.2 CD-ROM was manufactured. Additional important information, which was discovered too late to be put onto the release, can be found on NeXTanswers. Request NeXTanswers #2455 for the location of the most up-to-date release notes for a variety of NeXT's software products.

The NeXT OLE ORB

This document lists all of the API changes and some of the bug fixes relating to the NeXT ORB for this release.

New Features in This Release

Supporting Localization in OLE Automation

OLE Automation offers support for localization by allowing the developer to specify a locale when looking up the names of properties, or of methods and their arguments. In release 4.1, the NeXT ORB would always specify the default system locale for the machine it was running on when matching an OLE method or property to a given Objective-C method. As a result, the Objective-C protocols a client used to talk to an OLE server would depend on the host on which the server was running. For this reason, the ORB now has new methods which allow you to specify the language to use when connecting to OLE Automation objects. From Objective-C, instead of using:

-(id)objectWithRegisteredName:(NSString *)name

protocol:(NSString *)proto

host:(NSString *)hostName

you can now use:

-(id)OLEObjectWithRegisteredName:(NSString *)name

localeId:(unsigned long)localeId

host:(NSString *)hostName

From Visual Basic, the alternative to this standard call:

orb.connectTo(name, protocol, host)

is:

orb.connectUsingOLE(name, localeId, host)

In the above, the localeId arguments are Win32 LCID's: 4-byte quantities which specify a primary language and sublanguage. (For more details see the Microsoft Win32 SDK documentation.) Common values are 0x9, for ªneutralº English, or 0x409 for North American English.

These new methods set the locale for the returned object. Also, the locale propagates recursively to all objects returned from that one.

Bugs Fixed in This Release

Supporting ªOldº DO

In OPENSTEP 4.1, OLE clients were unable to connect to Objective-C servers using ªoldº (NXConnection-based) DO. This has been fixed in

release 4.2. However, this fix involves a change to the file nxorb.m (shipped on Windows systems in the directory NextDeveloper/Libraries). If you want Objective-C and OLE Automation objects to communicate using old DO, your Objective-C programs must be re-linked against the new version of this file.

Enterprise Objects Framework 2.1

This file describes new product features and explains how to install the examples. It does not contain complete release notes for release 2.1 of Enterprise Objects Framework. Complete release notes are installed when you install EOF 2.1.

For the 2.0 release notes (which include a lot of information that's still relevant for 2.1), see NeXTanswer #2455. If you have access to the World Wide Web, you can look up the URL http://www.next.com/NeXTanswers/HTMLFiles/2455.htmld/2455.html.

The documentation supplied with this release is 2.0 documentation. The 2.1 documentation will be made available when the product is released.

The MachOS version of this release is 3-way fat; it can be used to develop software for NeXT, Intel, and SPARC. The OpenStep for Windows version of this release can be used to develop software for Intel machines running Windows NT.

New Features for 2.1

- You can add methods to your interface in Interface Builder to perform queries and calculations on a specified class property.
- You can associate a qualifier with a display group in Interface Builder.
- Interface Builder allows you to set a fetch limit.
- You no longer have to add key paths as strings in Interface Builder-- instead, you can traverse the object graph in the Inspector to connect to the desired property.
- There is a new EOComboBoxAssociation.
- There is a new EOArrayDataSource class.
- EOModeler has a new "Explorer" outline interface that makes model traversal easier.
- When you connect a control to a display group in Interface Builder, a formatter is automatically added to the control based on the associated property's data type.
- There is a new Enterprise Objects Framework wizard that automates the creation of simple Enterprise Objects Framework applications. When you create an application in Project Builder, you have the option of either creating a conventional Enterprise Objects Framework application or using the wizard to automate application creation.
- EOModeler provides an Inspector for editing the connection dictionary.
- The Diagram View in EOModeler, formerly just an example, is now a part of the product.
- The Enterprise Objects Framework examples have been updated.
- The Oracle and Informix adaptors link with the newest client libraries.
- The new Oracle login panel is designed to work with SQL*Netv2.

Installing the Examples

This release provides on-line examples to help familiarize you with Enterprise Objects Framework 2.1. These examples are located in /NextDeveloper/Examples/EnterpriseObjects. Installing the examples involves these steps:

- Setting up users and databases on your database server for the example databases.
- Installing the example directory.
- Populating your database server with example data.

Note: When installing the examples for use with the Informix adaptor, use EOModeler's Connection Dictionary Inspector to set "databaseEncoding" to "Non-lossy ASCII" for the Movies and Rentals models. This will allow Enterprise Objects Framework to insert records with non-English characters.

Setting up Database Accounts

The Enterprise Objects Framework 2.1 examples use two sets of tables: Movies and Rentals. Some examples use just one of the these databases, while others use both. The multi-database support in Enterprise Objects Framework 2.1 makes it possible for you to install these databases in three different configurations:

- Both sets of tables together in a single user/database.

- Each set of tables in its own user/database on the same database server.
- Each set of tables on its own database server (for example, Movies on Informix, Rentals on Oracle).

Depending on your desired setup, you use the tools available with your database server to set up one or two new user/databases. For example. on Sybase you might create a new database on your server called ªMoviesº and login with the user ªsaº. On Oracle you might create a new user with the name ªMoviesº. Once you have set up these accounts, you're ready to install the examples.

Copying the Example Directory

To configure and build the examples you need to copy the example directory to a writable area in your file system. You can do this by copying the /NextDeveloper/Examples/EnterpriseObjects folder into your home directory (or any other directory writable by you).

Configuring the Example Models

The model files used by the examples must be configured to use your adaptor and server. To configure the examples, run the configure_examples program in your copy of the examples directory. It will ask you for the name of the adaptor you wish to use (Informix, Oracle, Sybase, and so on) and for the login information for your database. It will then convert the example models for your server.

Populating the Databases

Now that the examples are configured, you can fill your example databases with sample data. The install_database tool in the DatabaseSetUp directory will connect to your databases, add the example tables, and fill them with data. If you later wish to remove the data, simple run the drop_database tool.

Building the Example Programs

With your example projects installed and your database filled with data, you are ready to build and run the examples. To do this, in a command shell cd to your example directory and type make all. This performs a make install on BusinessLogic.framework and EOExtensions.framework to put them in /LocalDeveloper/Frameworks, where they are shared by many of the other examples. It then makes all of the examples applications.

Note: The /LocalDeveloper/Frameworks directory must be created and writable by you in order to build the examples. On Mach this can be accomplished by using su to become the superuser and then executing the following commands:

mkdirs /LocalDeveloper/Frameworks

chmod a+w /LocalDeveloper/Frameworks

Project Builder Software Configuration Management Extensions

Overview

Project Builder can now be extended to support interaction with third-party Software Configuration Management (SCM) systems. This is done by loading ªSCM Adaptor Bundlesº into Project Builder; these bundles plug into Project Builder's public SCM programmatic interface. OPENSTEP 4.2 on Windows includes a bundle that allows you to interact with INTERSOLV's PVCS Version Manager product. On both Mach and Windows, an unsupported bundle supports the GNU Concurrent Version System (CVS). Both integrations make use of the same GUI extensions to Project Builder, but invoke different sets of SCM operations that are specific to the SCM system under which the current project lives.

INTERSOLV Polytron Version Control System (PVCS)

The PVCS_Support bundle requires that PVCS Version Manager be installed on each machine that uses it. This integration has been tested on the current version on PVCS, which is 5.2.20. It will also work with Intersolv's upcoming release of PVCS Version Manager 5.3 (it's also possible that later versions of PVCS will work using this integration bundle). PVCS can be obtained directly from Intersolv:

1700 NW 167th Place

Beaverton, OR 97006

1-800-547-4000 (General Phone)

1-800-443-1601 (Tech Support Phone)

Other SCM Products

The CVS_Support bundle requires the public-domain CVS package that can be found at many popular ftp sites on the Internet. While it has proven useful in some organizations, it is not a supported configuration management product and it does have its limitations.

Support is planned for other popular SCM products that are accessible from Mach or Windows. Please contact NeXT Product Marketing regarding future plans and schedules of SCM integrations with Project Builder.

Using an SCM Adaptor Bundle

Before using an SCM Adaptor Bundle from Project Builder, you must configure Project Builder to load the bundle at startup and you must set up the defaults database to specify your integration preferences.

Configuring Project Builder

To configure Project Builder to load an SCM bundle at startup, launch Project Builder and select Preferences from the main menu. In the Bundles pane of the Preferences panel, click Add; this brings up a file browser that allows you to select the location of the bundle. Select the PVCS or CVS bundle, as appropriate, from $(NEXT_ROOT)/NextDeveloper/PBBundles. Then, re-launch Project Builder<this causes the bundle to load and take effect.

Setup Defaults

You'll need to set some defaults in order to configure Project Builder to work with SCM. You may either use the SCM Preferences panel to set these defaults, or you may open a terminal and enter the defaults manually. If using a shell (such as the Bourne shell; defaults cannot be set from an MS-DOS prompt), enter the following commands to set the SCM defaults (replace any information in italics with your local information):

...If you're using PVCS:

defaults write ProjectBuilder PVCSDefaults '{path="PVCS_Executable_Path"; userName=unknown;}'

The following default should either be YES or NO, depending on whether or not you want to lock files automatically when you start to edit them in Project Builder.

defaults write ProjectBuilder lockOnEdit YES_or_NO

...If you're using CVS:

defaults write ProjectBuilder CVSDefaults '{path="CVS_Executable_Path";}'

Supported Operations

The SCM bundles support the following operations on files under SCM control:

- Create a new Work Directory from an existing Repository
- Add/Remove Files
- Lock/Unlock Files (PVCS only)
- Update Files
- Merge Files
- Tag Files
- Display History or Show Changes for Files

Some operations, such as creating a new repository or importing a project into it for the first time, must be performed using tools provided by the underlying SCM system.

PVCS User's Guide

Once you've configured Project Builder and the defaults database for use, you're ready to take your SCM system for a test drive. You may find the following guide helpful in getting started with Project Builder and PVCS:

OPENSTEP 4.2

PVCS Adaptor Bundle User's Guide

Overview

This document describes the usage of the Project Builder PVCS integration provided by the PVCS_Support bundle. It is assumed that you have access to the PVCS Version Manager product and its documentation.

Topics Covered

This tutorial covers the following topics:

- Layout of the "SCM" User Interface
- SCM Operations
- Creating a new Work Directory from an existing Repository
- Adding files to the Work Area
- Locking Files
- Checking in Changes
- Tagging Files
- Updating a Work Area
- Miscellaneous Operations

Before you begin...

Before following this tutorial, you must:

- Install INTERSOLV PVCS
- Configure the PVCS_Support bundle in PB and the defaults database
- Create a PVCS Repository

Note: When creating a repository with PVCS, using the "Project Assistant" is recommended. When prompted to add directories to the repository, make sure you "Add with Subdirs..." in order to incorporate all of the subdirectories in your project.

User Interface Layout

The SCM user interface consists of menu items, a main panel, and auxiliary panels. This section briefly describes the layout and functionality of

these widgets.

SCM Menu Items

Most of the SCM operations may be performed via the SCM menu items. The menu items are located under the "SCM" submenus of ProjectBuilder's "Project" and "File" main menus.

Project-->SCM

Show Panel

Displays the SCM Panel.

Show Console

Displays the SCM Console.

Create Work Directory

Displays the Create Work Directory panel.

Merge Files

Puts all project files into the SCM Panel and selects SCM's Merge operation in the panel.

Stamp Files

Puts all project files into the SCM Panel and selects SCM's Stamp operation in the panel.

Check In Files

Puts all project files into the SCM Panel and selects SCM's Check-In operation in the panel.

File-->SCM

Show Panel

Displays the SCM Panel.

Check In Files

Puts files selected in ProjectBuilder into SCM Panel and selects SCM's Check-In operation in the panel.

Lock Files

Puts files selected in ProjectBuilder into SCM Panel and selects SCM's Lock operation in the panel.

Unlock Files

Puts files selected in ProjectBuilder into SCM Panel and selects SCM's Unlock operation in the panel.

Stamp Files

Puts files selected in ProjectBuilder into SCM Panel and selects SCM's Stamp operation in the panel.

Show Changes

Diff's the files selected in ProjectBuilder with their corresponding repository head versions.

SCM Panel

Most of the SCM operations may also be performed via the SCM panel. To display the SCM panel if it's not already visible, click the Project-->SCM-->Show Panel menu item. The panel consists of five UI elements:

- Table View

- Update Status Button

- File Status Filter

- Miscellaneous Operation Buttons

- Core Operations Popup Button

Table View

The SCM table view contains rows representing a single file in the PB.project. The table view shows the files associated with the project in a flattened way, whereas ProjectBuilder arranges the files hierarchically in it's main project window. The first column of the table view shows the status of the files relative to the head of the repository. Since multiple users may be making changes to the repository, the status is never guaranteed to be totally up to date, although the statuses are sync'd with the head of the repository right when the project loads into ProjectBuilder. The second column in the table view displays the path of the file relative to the main project directory.

Update Status Button

Located in the upper right corner of the SCM panel is the "Update Status" button. The user may periodically click the "Update Status" button to update the local file statuses relative to a snapshot of the repository head at the time the update button is clicked.

File Status Filter

To the right of the table view, and below the "Update Status" button, is a file status filter popup button. The filter button indicates that only files with the given status will appear in the table view. For instance, to show only those files that are locally modified, select "Modified" in the filter popup button and the table view should change it's display to show only the files whose statuses equal "Modified". To show all files in the project, switch the filter popup button back to "All Files". Note that changing the filter does not run the status command, it just shows the currently known statuses.

Miscellaneous Operations Buttons

Below the filter setting you'll find miscellaneous operations buttons (Show Changes and Display History). See the Miscellaneous Operations section later in this document for information on these functions.

Core Operations Popup Button

Below the miscellaneous buttons you'll find the operation popup button. In order to perform an SCM operation you first need to select the files in the table view which you wish to operate on. Once you've selected the proper files, choose the operation you wish to perform in the operation popup and then click the "Execute" button. The operation will be performed and the output of the command will be written to the SCM console (display the console by clicking the Project-->SCM-->Show Console menu item). If there is a fatal error during the execution of the command the user will be notifiy via an alert panel. The user may also be prompted to enter additional information before the command is executed (like a check-in log message, for instance). See the sections later in this document relating to the SCM operations for more information.

SCM Auxiliary Panels

In addition to alert panels displaying important SCM errors, there exist a few auxiliary panels:

- SCM console

- Log Entry Panels

SCM Console

The SCM console, which displays pertinent repository log messages, may be made visible by clicking the Project-->SCM-->Show Console menu item. The console is read-only, but it may be cleared periodically by clicking the "Clear" button located at the lower right of the panel.

Log Entry Panels

The "Check-In" and "Stamp" log entry panels appear automatically when the respective "Check-in" or "Stamp" operations are performed. These panels prompt the user to enter a repository log message for each of these operations. See the Checking in Changes and Stamping Files sections later in this document for further information.

SCM Operations

The following sections describe SCM functionality for the following operations:

- Creating a New Work Directory
- Adding/Removing Files in the Work Area
- Locking/Unlocking Files
- Checking In Changes
- Stamping Files
- Merging the Work Area
- Miscellaneous Operations

Creating a New Work Directory

Follow these steps to create a new work directory:

- Display Create Work Directory Panel
- Set Work Directory and Repository Location
- Create and Open New Project

Display Create Work Directory Panel

Once you've created (and/or located) the source code repository, select Project-->SCM-->"Create Work Directory" from the ProjectBuilder main menu to create a new work area. This will bring up a panel that prompts you for the repository location and the local work directory location (the directory into which your local work area will be created).

Set Work Directory and Repository Location

You may click the "Set..." buttons next to the text fields on the panel in order to bring up a file browser will will allow you to graphically select the directories. You may also take advantage of path completion in the fields by typing a partial path and pressing your user defined path completion key (default is F2 on OpenStep/Windows).

Create and Open New Project

Once the directory information is complete, click "Create" to create and open the project. During the creation process, a local copy of the repository will be checked out into your local work directory, and the corresponding PB.project will be opened in ProjectBuilder. Once your local work directory is created you should never need to create it again. Simply opening an existing PB.project that was previously created with SCM should activate the SCM system for that project. An existing PB.project may be opened by either double-clicking on the PB.project file in the Windows file viewer, or by opening the project inside of ProjectBuilder via the Project-->Open... main menu item.

Adding/Removing Files in the Work Area

Whenever you add or remove files from the project using ProjectBuilder's add/remove files functionality, the SCM system is automatically notified

about the changes and acts accordingly.

Add Files

If you've added a file, SCM will add that file to the list it maintains for the repository and mark that file's status as "Added". You must select the file and "commit" the operation to write that file to the repository. If the operation is successful the file's status is set to "Up-To-Date".

Remove Files

When removing a file from the project, SCM immediately removes that file from the list it maintains and there is no need to commit the operation to the repository. Under PVCS files are never actually removed from the repository (they'll only be removed from the PB.project).

Locking/Unlocking Files

Lock Files

The PVCS source code repository system requires that users lock files in the repository that they are currently working on to prevent others from making changes to the files simultaneously. If you have your defaults set up correctly, the SCM bundle will lock files in PVCS automatically when you begin editing them in ProjectBuilder (see the section on setting up ProjectBuilder in the SCMReleaseNotes.rtf). In order to lock files manually, select the desired files in the table view, select "Lock" in the operation popup, and click the "Execute" button. This will lock the selected files and prevent others from modifying them in the repository. Note that if you attempt to lock a file that has a newer version in the repository, the lock will fail and the file status will be set to "Needs Update". See the section on Merging a Work Area later in this document if that situation occurs.

Unlock Files

You can unlock files in two different ways:

1. Select the files and then "Unlock" them using the SCM panel operation.

2. Check-In the desired locked files - if the check-in is successful the files will automatically be unlocked.

Checking in Changes

Follow this process to check in changes:

- Identify and Verify Modified Files

- Execute Check-In Operation

Identify and Verify Modified Files

If you have locally modified files (status equals "Modified") you may elect to check your changes into the repository. The file status must also indicate that the file is "Locked" (status should read "Locked and Modified") since PVCS requires files to be locked before check-in. If the file isn't locked (status just says "Modified"), select the unlocked/modified files in the table view and then choose "Lock" in the operation popup. Click the "Execute" button to lock the files. Once the files are locked you will be able to proceed with the check-in only if you have the latest version of the files checked out. If you don't, the file status will read "Needs Update". Select the files needing update in the SCM table view and execute the "Merge" operation to update the files (see the section Merge Work Area later in this document). Once this checklist is complete you should be able to check in the files.

Execute Check-In Operation

Select the modified/locked files in the SCM table view, select "Check In" in the operation popup, and click the "Execute" button. A log panel will open prompting you to enter a log message describing the changes you are about to check in. After you've entered your message click 'OK' and the check-in will occur. If you click 'Cancel' the check-in will be aborted.

Stamping Files

You may elect to stamp a set of files in order to distinguish the current versions in some special way. For instance, you might stamp the files in your project with "Release01" to indicate that the current repository versions correspond to "Release01" of your software. In order to stamp your files select the desired files in the table view, choose "Stamp" in the operation popup, and click the "Execute" button. A panel will appear prompting you to enter a string which will be used to identify the stamp. Enter something in the text field and click 'OK' to proceed. If you click 'Cancel' the operation will be aborted.

Merge a Work Area

You may elect to merge the contents of the repository head into your local files. The need to do this would arise if someone else checked-in changes to the repository which you haven't incorporated yet. If your file statuses have been updated recently enough, files that are in an intermediate state which requires updating will have their files statuses set to "Needs Update". To update your local files select the desired files in the table view, select Merge in the operation popup, and then click the "Execute" button. Ideally, the SCM system will be able to perform the merge without conflicts. However, if you revert the merged file to saved and find that the merge resulted in conflicts, you'll need to fix the conflicts before you attempt to check in your changes.

Miscellaneous Operations

Show Changes

The "Show Changes" button on the SCM panel will launch FileMerge and diff the files selected in the SCM table view relative to the corresponding repository head versions of those files.

Display History

The "Display History" button will display the repository history information (in the SCM console) on the selected files in the SCM table view. In order to view the history the SCM console must be visible. To make the console visible, click the Project-->SCM-->Show Console menu item.

CVS Note

With the CVS Adaptor, you must have the CVSROOT environment variable set for Project Builder to inherit. The repository path you specify when creating a new CVS work area (which is currently necessary to use the integration) must be relative to the CVSROOT path<it cannot be absolute.

Known Bugs and Limitations in the SCM Integrations

Reference: 1463

Issue: File and Project RENAME not supported

Description: Renaming files or projects under SCM control is not supported. Attempting to do so will result in a confused SCM state.

Reference: 1647

Issue: Checking in files sometimes makes them write protected

Description: Occasionally the user may be prompted to overwrite a read-only file or revert a file to saved. These alerts occur mainly because the revision control system is writing to the files without Project Builder's knowledge. In general it is acceptable to revert or overwrite the files and continue working. This issue will be fixed in the next release.

Bugs Specific to PVCS Integration

Currently, there are no known bugs specific to the integration with PVCS.

Bugs Specific to CVS Integration

Reference: 1482

Issue: Updating a file that has been added (but not committed) changes status to up-to-date

Description: If a file is added to a project and then updated before it is checked in, the file status is incorrectly changed to "Up-To-Date" instead of remaining "Added".

Workaround: Check-in added files before you perform any other SCM operations on them.

Reference: 1606

Issue: If there is a lock on the repository SCM will hang forever

Description: If there is a lock on the CVS repository, the SCM adaptor (and hence Project Builder) will hang indefinitely.

Workaround: Manually remove the lock from the CVS repository and restart Project Builder if necessary._

Supplemental User Notes

Most information useful for users is located in the printed user release notes. Additional notes that are relevant to both end-users and developers are listed here.

Sound.app Can Crash Workspace Manager

Sound.app has a bug that can cause Workspace Manager to crash. If Sound.app is the default application for a sound file, and you double-click that file, Sound.app will start<with an apparently blank sound (the title bar will show ªUntitledº). If you then drag the icon for the sound file from Sound.app's file well over the file viewer, Workspace Manager will report an error and you'll be automatically logged out.

TextEdit

TextEdit is a new application based on the new text system. In addition to the standard text editing features in the 3.3 Edit application, it provides:

· "Wrap to Page" mode. This mode causes the document to be wrapped to the current page size (as opposed to the window size), and thus shows you a simple WYSIWYG representation of your pages. This mode also allows zooming.

· Support for new text object features such as hyphenation, kerning, ligatures, and baseline offsets.

· Ability to read/write plain text files in different 8-bit character encodings and Unicode. Coupled with the Kanji support in the new text object, you can read/write/edit Kanji files created by 3.3J or 4.1J. (You will need Kanji fonts and input manager.)

The alternate encoding to apply to a file is specified by a popup in the Open or Save panels. The default item, "Default," tells TextEdit to use either the default 8-bit encoding of the system or Unicode. Other choices let you select different encodings. You can also set the default setting of this popup via the Preferences panel.

Sources to TextEdit are available with the developer software, in /NextDeveloper/Examples/AppKit/TextEdit.

Known Issues in This Release

Reference: None

Issue: Encoding popup in Open/Save panels not available under NT3.51

Description: Because accessory views aren't supported under NT3.51, there is no encoding popup in the Open/Save panels.

Workaround: You can use the popup in the Preferences panel to set the default choice for the popup, which will then be used when files are opened or saved.

In addition, please refer to the Application Kit release notes for the new text system bugs.

IBM ThinkPad 760ED OPENSTEP Driver Overview

This article discusses a device driver for the OPENSTEP Mach operating system, versions 4.0 through 4.2.
This article has been archived and is no longer updated by Apple.
Driver: IBM ThinkPad 760ED Display
Last Update: December 18, 1997

Availability Information

A version of this driver is on the OPENSTEP CD-ROM
An updated release version of this driver, version 4.03, is avaiable on Apple's FTP servers at:
ftp://ftp.info.apple.com/Apple_Support_Area/Apple_Software_Updates/MultiCountry/Enterprise/openstep/drivers/released/ThinkPad760ED.pkg.compressed

Driver Name / Installer .pkg: IBMThinkPad760EDDisplayDriver
Driver Type: Display
Driver Scope: Specific Product
Supported Components: Trident Cyber9382, Trident Cyber9385
PC Bus / Interface Supported by Driver*: Integrated

General Overview notes: This device driver supports the built in LCD for IBM Thinkpad 760E, 760ED and 560 systems. The external monitor is also supported in all modes.

Supported Products / Systems (ie integrated into PC System):
IBM ThinkPad 760E
IBM ThinkPad 760ED
IBM ThinkPad 560

Special Features of Driver / Driver Notes:
This device driver provides information in the Configure application's help panel. Choose Info>Help from the Configure menu and scroll down to find this device driver's help topic.

Display Driver Details

Supported Connectors: 15-pin High Density (VGA)
Access Mode: Linear Framebuffer
Adapter Memory: 1MB DRAM, 2MB DRAM

Display Modes (Number in () after resolution indicates frame buffer size required)

16 Bit Color Modes*:
1024x768 (2MB+), 640x480 (1MB+), 800x600 (1MB+)

8 Bit Color / Greyscale Modes*:
1024x768 (1MB+), 1280x1024 (2MB+), 640X480 (1MB+), 800x600 (1MB+)

Driver Version Notes

4.01 - Initial version of this driver
4.02 - Supports switching of display devices through "Fn-F7"
- Added support for 1280x1024 modes
- 70Hz modes replaced by 75Hz modes

* - Indicates information that is inclusive of the entire capability of this driver. Not all devices supported by this driver may include all features listed.
Published Date: Feb 20, 2012

EOF 2.1 Release Notes

This document contains the most up-to-date release notes for release 2.1 of Enterprise Objects Framework.
This article has been archived and is no longer updated by Apple.
The MachOS version of this release is 3-way fat; it can be used to develop software for NeXT, Intel, and SPARC. The OpenStep for Windows version of this release can be used to develop software for Intel machines running Windows NT. The PDO version of this release can be used to develop software for Solaris and HPUX.

These release notes are organized into the following sections:

· Information About Other Releases
· Notes specific to Windows NT Developers
· Database Client Libraries
· New Features in Release 2.1
· Installing the Examples
· Enterprise Objects Framework User Defaults
· Locating the Documentation for this Release
· Known Issues in Release 2.1

Note: Because release 2.1 of Enterprise Objects Framework is based on the same architecture as release 2.0, many of the subjects in this document are relevant to both releases. Consequently, the term "release 2.x" is used where a discussion applies equally to releases 2.0 and 2.1.

Information About Other Releases

This document describes the features introduced, the bugs fixed, and the known issues in Enterprise Objects Framework release 2.1.

For a description of the features introduced in Enterprise Objects Framework release 2.0, see the 2.0 release notes. They contain a lot of information that's still relevant for 2.1, including information about converting release 1.x applications to 2.0 and a list of features shared with Enterprise Objects Framework release 1.2.

For a description of how Enterprise Objects Framework 2.0 and 2.1 differ from the preceding releases, see the document *Differences Between Enterprise Objects Framework 1x and 2.0* in **/NextLibrary/Documentation/NextDev/EnterpriseObjects/1x_To_2**.

Notes Specific to Windows NT Developers

References to filenames in this document use UNIX format. On Windows NT, you can interpret these by reading backslashes for the slashes and adding the installation directory (**c:\\NeXT** by default) to the beginning. For example, **/NextLibrary/Documentation** on Windows NT is **c:\\NeXT\\NextLibrary\\Documentation**.

To use Enterprise Objects Framework on Windows NT, you must have the appropriate database client libraries. The Sybase client libraries are provided on the OpenStep Enterprise 4.2 CD as an optional package. To install the Sybase client libraries, you must do a custom installation and explicitly specify that you want to install the package. To use Enterprise Objects Framework with Oracle or Informix, you must purchase the appropriate client libraries from your database vendor.

Here's what you need:

Oracle

Phone: (800) 542-1170
Ask for: SQLNET v2.2 for PC/Windows NT

The Oracle adaptor on NT requires the Oracle 7.3 or 7.2 Client Library. It won't work with the 7.1 libraries.

Informix

Phone: (800) 331-1763
Ask for: ESQL/C version 7.2 for Win32

Notes Specific to PDO Developers

To use Enterprise Objects Framework on PDO, you must have the appropriate database client libraries.

Here's what you need:

Oracle

Phone: (800) 542-1170
Ask for: 7.3.2 SQLNet V2 TCP/IP Client libraries

Informix

Phone: (800) 331-1763
Ask for: ESQL/C Version 7.20.UC2

Sybase

Phone: (800) 685-8225
Ask for: OpenClient/C Version 10.0.4

On PDO applications must explicitly link against the adaptor framework and the client libraries. For an example of how to do this, see the makefiles in the example "SimpleFetch" in **NextDeveloper/Examples/EnterpriseObjects**.

Database Client Libraries

This section includes some tips on using database client libraries with Enterprise Objects Frameworks. It is organized by database vendor.

Oracle

On Windows NT, using the latest release of the client library (7.3) requires you to use SQL*Net v2, which requires a **tnsnames.ora** file. **tnsnames.ora** is a file that you put on client machines, generally in the directory **Orant/Network/Admin**. The file contains information needed to connect to a server over the network. Entries in **tnsnames.ora** are keyed off of a server ID alias, and they include information such as the server ID, the host machine name, and the network protocol used by the client library to resolve the server ID alias. An entry in **tnsnames.ora** might resemble the following:

myServerAlias = (DESCRIPTION=(ADDRESS=(PROTOCOL=tcp)
(HOST=myMachine) (PORT=1521))(CONNECT_DATA=(SID=eof)))

Oracle provides tools you can use to create **tnsnames.ora** files. Refer to your Oracle documentation for more information on **tnsnames.ora** files and the tools you can use to create them.

If you're using the 7.2 version of the Oracle client libraries on Windows NT or if you're using Mach clients (the Oracle client included in the Mach release is 7.2), you can use either SQL*Net v1 or SQL*Net v2. To use SQL*Net v1, you should set your adaptor's connectionDictionary **serverId** entry to "T:<host-machine>:<server-name>".

To use SQL*Net V2 on Mach clients, you should create a **tnsnames.ora** file and put it in the **/etc** directory.

Informix

If you get the error "INFORMIXSERVER not in sqlhosts file (25596)" but can connect to your database server using the Informix ilogin program, you may need to run SetNet32 to update the environment variables used by Informix.

The Informix client libraries appear to have redundant sources of server information. They use the **sqlhosts** file (**$INFORMIXDIR/etc/sqlhosts**) as well as a collection of environment variables managed by the Setnet32 program.

See your Informix documentation for more information on the sqlhosts file and the Setnet32 program.

New Features for 2.1

Integration with Project Builder and Interface Builder

· There is a new Enterprise Objects Framework Wizard that automates the creation of simple Enterprise Objects Framework applications. When you create an application in Project Builder, you have the option of either creating an empty Enterprise Objects Framework application or using the wizard to automate the creation of the user interface.

· Interface Builder now has a "New Database Interface" command that invokes the Wizard to add a new interface to an existing project.

· You can display totals, averages, and other aggregate computations without writing any code. Interface Builder now allows you to form connections using special keys. For example, you can associate the maximum salary to a text field using the key **@max.salary**.

· You can create "query by example" user interfaces without writing any code. Using Interface Builder, you can connect user interface control objects to special keys such as **@query=.departmentName** or **@query>.budget**, and Enterprise Objects Framework constructs and applies qualifiers for them.

· In Interface Builder, you can specify a qualifier for an EODisplayGroup's EODatabaseDataSource using the Data Source Inspector.

· Interface Builder allows you to set a fetch limit for an EODisplayGroup's EODatabaseDataSource.

· You no longer have to manually add key paths to an EODisplayGroup in Interface Builder. Instead, you can use the Interface Builder's Inspector to traverse relationships and connect to the desired property.

· When you connect a user interface control to an EODisplayGroup in Interface Builder, a formatter based on the data type of the associated property is automatically added to the control.

· There is a new EOComboBoxAssociation.

· There is a new EOArrayDataSource class.

EOModeler

· EOModeler has a new "Explorer" outline interface that makes navigating the model easier.

· EOModeler provides an Inspector for editing the connection dictionary.

· EOModeler has a new Diagram View that helps you visualize relationships between entities.
· EOModeler supports cutting and pasting and model objects both within and between models. You can also drag and drop model objects within and between models.

· EOModeler supports quicker creation of EOModels by reading only the tables you specify.

Adaptors

· The Oracle and Informix adaptors link with the newest client libraries.

· The new Oracle login panel is designed to work more naturally with SQL*Netv2.

Framework

· The Framework supports whole-table caching for read-only entities, thereby avoiding redundant fetches of reference

data.

· Exceptions raised by the framework now contain more information. For example, validation exceptions include the object and property that failed validation, and update exceptions indicate the object and database operation that were involved in the failure.

Examples

· The Enterprise Objects Framework examples have been updated.

Installing the Examples

This release provides on-line examples to help familiarize you with Enterprise Objects Framework 2.x. These examples are located in **/NextDeveloper/Examples/EnterpriseObjects**. Installing the examples involves these steps:

· Setting up users and databases on your database server for the example databases.
· Installing the example directory.
· Populating your database server with example data.

Setting up Database Accounts

The Enterprise Objects Framework 2.x examples use two sets of tables: Movies and Rentals. Some examples use just one of the these databases, while others use both. The multi-database support in Enterprise Objects Framework 2.x makes it possible for you to install these databases in three different configurations:

· Both sets of tables together in a single user/database.
· Each set of tables in its own user/database on the same database server.
· Each set of tables on its own database server (for example, Movies on Informix, Rentals on Oracle).

Depending on your desired setup, you use the tools available with your database server to set up one or two new user/databases. For example. on Sybase you might create a new database on your server called ªMoviesº and login with the user ªsaº. On Oracle you might create a new user with the name ªMoviesº. Once you have set up these accounts, you're ready to install the examples.

Copying the Example Directory

To configure and build the examples you need to copy the example directory to a writable area in your file system. You can do this by copying the **/NextDeveloper/Examples/EnterpriseObjects** folder into your home directory (or any other directory writable by you).

Configuring the Example Models

The model files used by the examples must be configured to use your adaptor and server. To configure the examples, run the **configure_examples** program in your copy of the examples directory. It will ask you for the name of the adaptor you wish to use (Informix, Oracle, Sybase, and so on) and for the login information for your database. It will then convert the example models for your server.

Populating the Databases

Now that the examples are configured, you can fill your example databases with sample data. The **install_database** tool in the **DatabaseSetUp** directory will connect to your databases, add the example tables, and fill them with data. If you later wish to remove the data, simple run the **drop_database** tool.

Building the Example Programs

With your example projects installed and your database filled with data, you are ready to build and run the examples. To do this, in a command shell **cd** to your example directory and type **make all**. This performs a **make install** on **BusinessLogic.framework** and **EOExtensions.framework** to put them in **/LocalDeveloper/Frameworks**, where they are shared by many of the other examples. It then makes all of the examples applications.

Note: The **/LocalDeveloper/Frameworks** directory must be created and writable by you in order to build the examples. On Mach this can be accomplished by using **su** to become the superuser and then executing the following commands:

mkdirs /LocalDeveloper/Frameworks
chmod a+w /LocalDeveloper/Frameworks

Enterprise Objects Framework Defaults

This section lists the user defaults for which Enterprise Objects Framework checks and changes its behavior.

Defaults in the NSGlobalDomain

To change these defaults, issue a command such as the following from a shell:

defaults write NSGlobalDomain EOAdaptorUseBindVariables NO

EOFDebugEditingContext
Default is NO.
EOControl Layer will log every time an object is changed.

EOFDebugUndo
Default is NO.
Logs each time something is pushed on or popped off an undo list.
Also logs in [_EOUndoStack dealloc].

EOAdaptorDebugEnabled
Default is NO.
Logs for connection attempts, all transaction activity (begin, rollback, commit), and SQL statements (select, update, etc.).

EOProjectSourceSearchPath
An optional array of paths in which EOAccess searches for framework project directories that contain models.

EOAdaptorUseBindVariables
Default is YES.
Controls whether or not the SQL generation process will use bind variables (for Oracle and Informix).

EOOracleTableNamesSQL
SQL statement used to identify tables for the model reverse-engineering process.
Default is:

SELECT TABLE_NAME FROM USER_TABLES ORDER BY TABLE_NAME")

If you would like the model reverse-engineering to look at a different set of the tables, you can provide your own SQL statement, for example:

SELECT TABLE_NAME FROM USER_TABLES ORDER BY TABLE_NAME
WHERE TABLE_NAME not in ('MY_USELESS', 'FOO')

EOOracleUseNoWaitLocks
Default is NO.
Controls whether Oracle uses NOWAIT locks.

EOSybaseInterfacesFile
Default is unset.
If the default is set, the SybaseAdaptor initializes the client library to run with this interface the specified interfaces file.
This default is not applicable on Windows NT.

EOSybaseTableNamesSQL
This default can be used to change the default SQL used to determine the tables that are analyzed in creating a new model.
Default is

select name from sysobjects where type = 'U' or type = 'V'

EOSybaseAttributeSQL
SQL statement used to get the attribute information for a given table.
Default is

select a.name attr_name, b.type attr_type, b.name type_name, b.allownulls allownulls, c.type primary_key, a.length width, a.prec prec, a.scale scale from syscolumns a, systypes b, syskeys c where a.id = object_id('%@') and a.id *= c.id and (a.colid *= c.key1 or a.colid *= c.key2 or a.colid *= c.key3 or a.colid *= c.key4) and (c.type = 1 or c.type is null) and a.usertype = b.usertype and datalength(a.name) > 0 order by a.name

EOSybaseRelationshipSQL
Default is

select a.keycnt, b.name tname, c.name cname, d.name dtname, e.name dcname from syskeys a, sysobjects b, syscolumns c, sysobjects d, syscolumns e where (b.type = 'U' or b.type = 'V') and a.depid is not null and a.depid > 0 and b.id = a.id and b.id = c.id and ((c.colid = a.key1 and e.colid = a.depkey1) or (c.colid = a.key2 and e.colid = a.depkey2) or (c.colid = a.key3 and e.colid = a.depkey3) or (c.colid = a.key4 and e.colid = a.depkey4)) and d.id = a.depid and d.id = e.id order by b.name, d.name

EOSybaseStoreProcedureSQL
Default is

select name, id from sysobjects where type = 'P'

EOSybaseStoredProcedureDetailsSQL
Default is

sp_sproc_columns %@

InformixINFORMIXSERVER
No default value.
The name of the Informix server.

InformixInformixTableNamesSQL
This default can be used to change the default SQL used to determine the tables that will be analyzed in creating a new model.
Default is

select tabname, owner, tabid from informix.systables where (tabid > 99) and (tabname <> 'ANSI') order by tabname

Defaults in the EOModeler Domain

To change these defaults, issue a command such as the following from a shell:

defaults write EOModeler DisableInheritenceCheck YES

BundlesToLoad
If you write extensions to EOModeler, you can get EOModeler to load them by setting this default. This default is an array, so remember to include parentheses when you set it. For example:

defaults write EOModeler BundlesToLoad "(/LocalDeveloper/ModelerBundles/MyModelerBundle.bundle, $HOME/eoexamples/ModelerBundle/ModelerBundle.bundle) "

RECORD_FETCH_LIMIT
Default is 100.
For the Data Browser in EOModeler. This controls how many rows to fetch before asking users if they want to fetch all, fetch another n rows, or just stop now.

Consistency Checks
All of the following defaults have the default NO:
DisableConsistencyCheckOnSave

DisableExternalNameCheck
DisableInheritenceCheck
DisablePrimaryKeyCheck
DisableRelationshipCheck
DisableStoredProcedureCheck

SkipBeautifyNamesOnModelCreation
Default is NO.
Setting this default to YES will cause EOModeler to leave the entity names and attribute names matching the exact names of their corresponding database objects (including the case).

DisableAdvancedOptions
Default is NO.
If set to YES, the EOModeler runs in "Simplified mode". The advanced inspectors don't appear, the choices of table view columns is limited, and so on.

Locating the Documentation for this Release

The documentation for this release is provided in PDF and Windows Help formats. On Windows NT, you can view documentation by choosing OPENSTEP Books On-Line from the OPENSTEP Enterprise program group. You can also find the documentation in the following on-line locations:

· The *Differences Between Enterprise Objects Framework 1x and 2.0* document describes how the product has changed between the 1x and 2.0 releases. See **/NextLibrary/Documentation/NextDev/EnterpriseObjects/1x_To_2**.

· *Using Enterprise Objects Framework with OPENSTEP* provides a tutorial and information on creating an Enterprise Objects Framework application on OpenStep. In addition to the hard copy book, a version of the book is provided on-line in PDF format. See **/NextLibrary/Documentation/NextDev/EnterpriseObjects/UsingEOFwithOS**.

· The *Enterprise Objects Framework Developer's Guide* provides a conceptual overview of the product. In addition to the hard copy book, a version of the book is provided on-line in PDF format. See **/NextLibrary/Documentation/NextDev/EnterpriseObjects/Guide**.

· The *Enterprise Objects Framework Reference* includes class specifications for the Enterprise Objects Framework classes. Reference documentation is located in **/NextLibrary/Frameworks** in one of these locations:

/EOAccess.framework/Resources/English.lproj/Documentation/Reference
/EOInterface.framework/Resources/English.lproj/Documentation/Reference
/EOControl.framework/Resources/English.lproj/Documentation/Reference
/InformixEOAdaptor.framework/Resources/English.lproj/Documentation/Reference
/ODBCEOAdaptor.framework/Resources/English.lproj/Documentation/Reference
/OracleEOAdaptor.framework/Resources/English.lproj/Documentation/Reference
/SybaseEOAdaptor.framework/Resources/English.lproj/Documentation/Reference

If You Need a PDF Reader...

PDF readers for various platforms can be found on the OPENSTEP Enterprise CD-ROM in the /3RD_PRTY directory. Or, you can download one from one of the following web locations:

· For Windows or Solaris: **http://www.adobe.com/acrobat/**
· For NEXTSTEP: **http://www.BITart.com/PDFView/**

Note: If you're using the Acrobat Reader to view PDF files on Windows NT, some text may initially appear as gray lines. If this happens, you can fix it by choosing File -> Preferences -> General. In the General Preferences panel, uncheck the Greek Text option.

Other Documentation

Depending upon your application, the *OpenStep Conversion Guide* may also provide useful information to you. It

discusses how to use the automated conversion process to convert applications to OpenStep. See **/NextLibrary/Documentation/NextDev/Conversion/ConversionGuide**.

Known Issues in Release 2.1

This section describes known issues with release 2.1 of Enterprise Objects Framework. It is organized into the following sections:

· Access Layer
· Control Layer
· Interface Layer
· Miscellaneous Framework
· Informix Adaptor
· Oracle Adaptor
· Sybase Adaptor
· EOModeler
· On-line Examples
· Documentation

Access Layer

These issues exist in the access layer of this Enterprise Objects Framework release:

Reference: 77935

Issue: EOModelGroup's **setDelegate** method doesn't work correctly.

Description: **setDelegate** builds a lookup list to determine which methods the delegate implements. Unfortunately in the case of **subEntityForEntity:primaryKey:isFinal:** it checks the selector **subEntityForEntity:primaryKey:**.

Workaround: Have the delegate implement a dummy method **subEntityForEntity:primaryKey:**.

Reference: 77886

Issue: There are severe performance issues when you perform prefetching using hints or batch faulting

Description: The algorithm used for batch faulting and relationship prefetching for to-many relationships is O(n^2).This means that fetching 1000 records takes 100 times longer than fetching one tenth as many, rather than O(1) = 10x.

Workaround: You can use the statement [EODatabaseContext _setUseFastBatchAlgorithm:YES] to enable an alternative algorithm. Due to time constraints, this new algorithm has not been qualified as production quality.

Reference: 77721

Issue: Can't update rows containing string attributes with trailing spaces.

Description: The Enterprise Objects Framework adaptors automatically strip trailing spaces from string values fetched from the database. They also strip spaces on newly inserted strings before sending them to the database. This works fine until you fetch data that a non-Enterprise Objects Framework application inserted that contains trailing spaces. If that attribute is marked as "used for locking," Enterprise Objects Framework will be unable to update the row (because the version in the database is different from the space-stripped version in the snapshot).

Workaround: Do not mark columns that could contain trailing spaces as used for locking. Alternately, strip the spaces from the data in your server.

Reference: 77656

Issue: Firing a snapshot fault after replacing a to-many relationship locks up the application.

Description: if you replace a to-many property fault (with **nil** or with another array) and then invoke **saveChanges**, Enterprise Objects Framework goes into an infinite fault firing loop.

Workaround: Update a to-many relationship using the methods **addObject** and **removeObject**; do not replace it with **nil** or another array.

Reference: 77546

Issue: Inclusion of framework models in defaultModelGroup doesn't happen automatically on PDO.

Description: Applications on PDO that link with framewoks that include models don't automatically get the models put in the applications.

Workaround: Manually construct the the model group yourself at application initialization. For example:

```
EOModelGroup *group = [EOModelGroup new];

// repeat for each model containing framework used by app
NSBundle *bundle = [NSBundle bundleForClass:[SomeClassInFramework class]]
NSEnumerator *enumerator = [[bundle pathsForResourcesOfType:@"eomodeld" inDirectory:nil] objectEnumerator];
NSString *modelPath;
while (modelPath = [enumerator nextObject])
[group addModelWithFile:modelPath];

[EOModelGroup setDefaultGroup:group];
[group release];
```

Reference: 77631

Issue: If you're editing a model (in code or with EOModeler), sometimes an EORelationship will return **nil** from **inverseRelationship**, even though you just added the inverse relationship.

Description: The first time you ask an EORelationship for its inverse relationship, it searches all the relationships in its **destinationEntity** looking for an inverse. It caches the result of this search, and this cache does not always get invalidated when the relationships of the **destinationEntity** change.

Workaround: See the category on EORelationship in the **ModelerBundle/RelationshipExtras.m** example.

Reference: 77354

Issue: Issues saving changes to attributes with mutable custom value objects.

Description: Suppose you have a mutable custom value type, PhoneNumber, that implements methods such as **setAreaCode:** and **setPrefix:** to change an enterprise object's values. If you use such methods to modify an enterprise object's values and save changes, the enterprise object is not saved to the database.

Workaround: To use mutable value classes you must do three things:

1. In the PhoneNumber value class object, implement **isEqual:** to appropriately compare two instances.

2. If the PhoneNumber value is about to be modified, its owning enterprise object must invoke [self willChange] before the modification.

3. In your enterprise object class, you must implement a "set" method that copies rather than retains the object passed to it. For example:

```
- (void)setDayTimePhone:(PhoneNumber *)number {
[dayTimePhone autorelease]
dayTimePhone = [number copy];
}
```

#1 would be required, even in a perfect world. #2 is a requirement of the basic Enterprise Objects Framework architecture. #3 is a bug in Enterprise Objects Framework -- Enterprise Objects Framework should be passing enterprise objects a copy of their values, but instead it's passing the the same instance that's shared in the snapshot.

In general, the simplest workaround is to use **immutable** custom value objects.

Reference: 72619

Issue: EOAdaptorChannel does not inherit EOAdaptor's delegate.

Description: According to the EOAdaptorChannel class specification and header file, the EOAdaptorChannel's delegate should automatically be kept in synch with its adaptor. Indeed, if a new delegate is assigned to an EOAdaptor, the new delegate is propagated to any of that adaptor's existing contexts and channels. However, if you create an EOAdaptor, assign a delegate to it, and then create EOAdaptorContexts and EOAdaptorChannels, the newly-created contexts and channels don't have the delegate assigned to them.

Workaround: Wait until all of the channels and contexts are instantiated before assigning the adaptor's delegate, or reassign the adaptor's delegate each time a new channel or context is created.

Reference: 61475

Issue: Enterprise Objects Framework performs less efficient deep fetches for single-table inheritance mappings than it should.

Description: To perform a deep fetch, Enterprise Objects Framework performs a fetch for each concrete class in an inheritance hierarchy. For a single-table inheritance mapping, Enterprise Objects Framework should perform only one fetch and then sort the results in memory. For example, if Person, Employee, and Customer objects are stored in one table<the PERSON table<the Framework should perform one fetch on the PERSON table to fulfill a deep fetch request of Person, Employee, and Customer objects. Instead, it performs three fetches: one to get Person objects, one to get Employee objects, and another to get Customer objects.

Workaround: Define only one entity for the entire inheritance hierarchy, and use the EOModelGroup delegate methods **subEntityForEntity:primaryKey:isFinal:**, and **entity:classForObjectWithGlobalID:** to create instances of the proper subclasses from database rows.

Reference: 74251

Issue: Changes made during **saveChanges** are silently lost.

Description: If you change an enterprise object while its editing context is in its **saveChanges** method (for example, if you change an enterprise object in an EODatabaseContext delegate method), the changes may be silently lost.

Workaround: Don't make changes to objects during the save process. Instead, make the changes from the EOEditingContext delegate method **editingContextWillSaveChanges:**.

Reference: 74345

Issue: You can't update to-many relationship if the foreign key isn't marked as a class property or as used for locking.

Description: Suppose that an entity's foreign key attribute isn't marked as a class property or as used for locking. If you designate the foreign key attribute as a to-many relationship's destination key, the foreign key value isn't always updated. This occurs because the destination entity doesn't know that the attribute participates in a relationship. Therefore, the destination entity doesn't fetch the foreign key from the database or update it.

Workaround: Mark attributes that are destination keys of a to-many relationship so they are fetched. For example, you could:
· Mark them as class properties.
· Mark them as used for locking.
· Use them in inverse relationships to the problematic to-many's source entity.

Reference: 74379

Issue: EODatabaseContext can't be the direct parentObjectStore of an EOEditingContext.

Description: The EODatabaseContext requires that an EOObjectStoreCoordinator sit between it and any EOEditingContexts that it serves. This is the default configuration set up by the framework, so you shouldn't normally run into this issue. Just a reminder, you can set up an editingContext and be ready to go with this one line:

```
EOEditingContext *editingContext = [EOEditingContext new];
// automatically uses [EOObjectStoreCoordinator defaultCoordinator]
// as parentObjectStore
```

Any necessary EODatabaseContexts are created and registered automatically.

Workaround: Don't assign an EODatabaseContext as the parentObjectStore of an EOEditingContext. There's no benefit to doing so anyway.

Reference: 76526

Issue: Applying a qualifier with key path to top of horizontally mapped inheritance hierarchy generates invalid SQL.

Description: Enterprise Objects Framework's query building mechanism doesn't handle relationships to inheritance hierarchies. For example, suppose that you are are attempting to qualify a fetch through a to-many relationship (**planes**) that points to the top of a horizontally mapped inheritance hierarchy (for the entities Plane, FighterPlane, and TrainerPlane). If you want the query to test against all tables, you'd expect Enterprise Objects Framework to generate SQL similar to the following:

```
SELECT t0.AIRPORT_ID
FROM PLANE t1, FIGHTER t2, TRAINER t3, AIRPORT t0
WHERE
(t1.LENGTH <= 1000 AND t0.AIRPORT_ID = t1.AIRPORT_FK) OR
(t2.LENGTH <= 1000 AND t0.AIRPORT_ID = t1.AIRPORT_FK) OR
(t3.LENGTH <= 1000 AND t0.AIRPORT_ID = t1.AIRPORT_FK)
```

Instead, Enterprise Objects Framework generates the following SQL:

```
SELECT t0.AIRPORT_ID
FROM PLANE t1, AIRPORT t0
WHERE
(t1.LENGTH <= 1000) AND
t0.AIRPORT_ID = t1.AIRPORT_FK
```

In other words, only the table for the root of the hierarchy is queried.

Workaround: You can create a qualifier that generates the correct SQL by:

1. Adding relationships in the source entity to all the tables in the inheritance hierarchy. For example, to the Airport entity, you'd add the relationships **toFighters** and **toTrainers** to the destination entities FighterPlane and TrainerPlane, respectively. Mark the relationships so they aren't class properties.
2. When building your query, explicitly list these extra relationships. In the Planes example, you'd fetch from Airport where "planes.length < 1000 OR toFigtherPlanes.length < 1000 OR toTrainerPlanes.length < 1000"

Alternatively, you might be able to solve this issue more generally by writing a post processor for EOQualifiers that splits up clauses that perform inheritance tests. The post processor could even programmatically generate the additional relationships on demand and register them with the model using names like "plane_Subclass_Fighter".

A generic EOQualifier post processor could be wired into Enterprise Objects Framework so that application writers don't have to know it exists. The right place for such a mechanism is probably in EOKeyValueQualifier's **schemaBasedQualifierWithRootEntity:** method (see EOSQLQualifier.h). You could put the post processor code in a subclass of EOKeyValueQualifier (with an appropriate call to **super** after the transformation, if any, is performed) and have your subclass pose as EOKeyValueQualifier.

Reference: 47832

Issue: Enterprise Objects Framework can't update attributes whose internal types are custom (such as NSImages).

Description: A custom value class must implement **isEqual:** to be used for attributes marked as used for locking.

Workaround: Implement **isEqual:** in the custom value class or don't mark the attribute as used for locking.

Reference: 65078

Issue: Seemingly innocuous qualified fetch always causes exception.

Description: Some qualified fetches raise exceptions because values in the SQL have been formatted as strings when they should have been formatted as some other type. This can happen when you enter an invalid external type or when a Sybase model doesn't contain information about user-defined types that are used in the model.

Workaround: In the case of an invalid external type, simply correct it. In the case of a user defined type, create a new model by reverse engineering the database. The new model's connection dictionary contains information about user-defined types. Copy the connection dictionary from the new model to the original one.

Reference: 69039

Issue: Alert panel displaying adaptor error is never dismissed.

Description: This occurs whenever an adaptor operation that was invoked from an **awakeFromNib:** method displays an alert panel. The issue is that the entire object graph is not yet instantiated when **awakeFromNib:** is invoked.

Workaround: Database operations should be begun from the **applicationDidFinishLaunching:** method rather than the **awakeFromNib:** method. Of course, this means that any methods that indirectly cause database communication should also be invoked from the **applicationDidFinishLaunching:** method.

Reference: 76885

Issue: The set of valid values for the **databaseEncoding** entry of a connection dictionary are not documented, and the set can vary in different locales.

Description: A connection dictionary's **databaseEncoding** entry contains the localized name for the string encoding. The localized names are not documented. Furthermore, the localized names for string encodings can vary with the user's locale. Consequently, the specified encoding for an application might not work for users in different locales.

Workaround: You can find the localized name for string encodings in **/NextLibrary/Frameworks/Foundation.framework/Resources/*language*.lproj/EncodingNames.strings**.

Reference: 59472

Issue: Derived attributes are limited and don't offer full SQL as advertised.

Description: Placing a string or a numeric constant in the definition field of a derived attribute generates invalid SQL. Definitions such as ªtitleº and ª0.0º don't work correctly. However, definitions such as ªatt1 + 5º should work correctly when ªatt1º specifies another attribute.

Workaround: None.

Reference: 70049

Issue: EOModelGroup doesn't raise an exception when more than one entity has the same name.

Description: Although it is illegal to have the same entity name in two different models in a model group, EOModelGroup doesn't check to see if this is the case when adding a model.

Workaround: Manually verify that no two models have entities with the same name or write a method to perform the check.

Reference: 70260

Issue: Some error messages returned by the Framework's default validation methods (such as methods that check that a value doesn't exceed the maximum width specified in its attribute) aren't localized.

Workaround: Implement an exception handler for use with the EOEditingContext, and have the handler replace the error messages with localized strings.

Reference: 76152

Issue: Inserting and deleting objects involved in inverse, to-many relationships can be very slow.

Description: Suppose that a ServiceRequest has a to-one relationship to its CustomerServiceRepresentative, and that the CustomerServiceRepresentative has an inverse to-many relationship to its ServiceRequests. When you assign a request to a representative using **addObject:toBothSidesOfRelationshipWithKey:**, you fire the fault for the **CustomerServiceRepresentative.serviceRequests**. So, if a representative has a large number of requests, assigning a new request to a representative can be very slow. Correspondingly, when you delete a request, Enterprise Objects Framework fires the corresponding representative's **serviceRequests** fault so it can remove the request from the array.

Workaround: Set the inverse, to-many relationship so it isn't a class property. For example, in the above request-representative scenario, you would remove the **serviceRequests** relationship from the class properties of the CustomerServerRepresentative entity.

Control Layer

These issues exist in the control layer of this Enterprise Objects Framework release:

Reference: 77714

Issue: Qualifier for **nil** to-one relationship always returns no matches.

Description: If you want to fetch all employees without a department, you'd expect to be able to use the qualifier:

"toDepartment = nil"

Currently, this will always (incorrectly) return no matches because it's testing the primary key on the other side of the relationship rather than the foreign key on the employee side. This is a bug in the EOQualifier method **schemaBasedQualifierWithRootEntity:** when it translates object references to foreign key references.

Workaround: Query explicitly on the foreign key in the Employee object. For example, "deptID = nil". This works even if deptID is not a class property of Employee. Note, however, that in this case the qualifier only works when run against the database, not for in-memory evaluation.

Reference: 77668

Issue: **EOArrayDataSource.h** isn't imported by **EOControl.h.**

Workaround: Explicitly import **EOControl/EOArrayDataSource.h** in your code.

Reference: 68146

Issue: Fault failure leaves EOInterface layer unstable.

Description: If a displayed enterprise object has a to-one relationship to a non-existent destination row, attempting to access the destination object raises an exception and corrupts the state of user interface objects. (Enterprise Objects Framework raises an exception when a to-one relationship cannot be resolved due to a referential integrity issue in the database).

Workaround: See the chapter "Advanced Enterprise Object Modeling" in the *Enterprise Objects Framework Developer's*

Guide for information on handling optional to-one relationships.

Reference: 64084

Issue: Inserted enterprise objects don't get removed from EODisplayGroup after sending **revert** to EOEditingContext.

Description: If you fetch objects into an EODisplayGroup, insert a few objects, delete a few objects, and then update a few objects; telling the EOEditingContext to revert backs out the updates, but not insertions or deletions. The actual insertions and deletions have been reverted, but the EODisplayGroup doesn't know how to revert its object list (since is doesn't keep track of what its original object list was before the insertions and deletions).

Workaround: Programmatically tell all affected EODisplayGroups to refetch after telling the EOEditingContext to revert, or use **refetch:** (**invalidateAllObjects:**) instead of revert.

Reference: 72177

Issue: Deleted objects are still registered in the EOEditingContext after a **saveChanges** operation.

Description: If an object is deleted in the EOEditingContext and then the EOEditingContext is saved, the deleted object isn't forgotten by the EOEditingContext (i.e., sending the EOEditingContext the message **objectForGlobalID:** should return **nil**, but it doesn't).

Workaround: Fortunately, this should have no affect on most applications. However, if you need to work around this issue, remember the deleted objects in the **editingContextWillSaveChanges:** delegate, and then invoke **forgetObject:** for each object after a successful save.

Reference: 72269

Issue: You can't tell Enterprise Objects Framework to not undo your changes when delete propagation fails.

Description: The EOEditingContext delegate method **editingContextShouldUndoUserActionsAfterFailure:** is supposed to allow programs to indicate that they do not want user actions undone if a validation or delete propagation error occurs. However, the EOEditingContext undoes the user action regardless of the return value from the method.

Workaround: None.

Reference: 72903

Issue: Aborted deletions are incorrectly recorded in the undo stack as empty undos.

Description: When the deletion of an object fails due to a deny rule, the undo manager records an empty undo group. This means that although nothing actually happened during the operation, the operation still needs to be undone before previous operations can be undone. For interactive programs this is not normally an issue since users rely on visual cues to determine how many times to undo. However, this may be an issue for code that programmatically performs undo operations.

Workaround: None.

Reference: 74965

Issue: The EOEditingContext delegate method **editingContext:shouldPresentException:** isn't called when **saveChanges** is invoked programmatically.

Description: If you use the following code:

```
eo = [[[Movie alloc] init] autorelease];
[eo setTitle:nil]; // Assume that the TITLE column doesn't allow NULLs
[editingContext insertObject:eo];
```

[editingContext saveChanges];

the **editingContext:shouldPresentException:** delegate method isn't called. Instead, an exception is raised.

However, if you instead set a user interface control object as the target for the editing context's **saveChanges:** action, the delegate method is invoked.

Workaround: Always use **saveChanges:** instead of **saveChanges**. If you don't have an argument to pass, just use

[editingContext saveChanges:nil];

Reference: 76466

Issue: EOEditingContexts don't propagate uninserts.

Description: Propagate delete works fine for an object that that is fetched from the database. However, if an object is created and inserted in an editing context and then deleted (thus never being saved to the database), the delete isn't propagated to the destinations of the object's relationships. For example, suppose you create an ExpenseReport object and several LineItems for it. If you then delete the ExpenseReport, the delete doesn't propagate to the LineItems. If the LineItems can't exist without an owning ExpenseReport, EOEditingContext's **saveChanges** fails when the delete is performed within the same event as the insert.

Workaround: Call [editingContext processRecentChanges] before deleting the previously inserted object.

Reference: 76901

Issue: Associations are refreshed too early when the fetch limit panel is raised, possibly causing an exception.

Description: Suppose you have two EODisplayGroups that are set to fetch on load. If the second display group to fetch exceeds the fetch limit, an alert panel inquiring whether to continue the fetch pops up. Presenting the panel causes the run loop to flush the first display group's user interface drawing. If the first display group's user interface displays enterprise object properties via key paths, EOFaults may be fired. Since the default EODatabaseChannel is busy with the fetch for the second display group, an exception is raised because there isn't an available channel.

Workaround: There are three workarounds:

1. Don't use the fetch "prompt on limit" feature.
2. Implement your own fetch limit panel that doesn't invoke a modal event loop.
3. Register an additional EODatabaseChannel with the EODatabaseContext so the fetch of the faults can occur while the second EODisplayGroup fetch is paused.

Reference: 77181

Issue: The EOQualifier contains operator doesn't do SQL generation.

Description: The contains operator is meant to do to-many array comparison. For example, you might query on the Studio entity using the following qualifier format:

"movies contains %@", someMovieObj

The resulting qualifier works for an in-memory search, but doesn't generate SQL for a database search.

On the other hand, using the equality operator for to-many array comparison kind of works in SQL, but not in memory. For example, you might query on the Studio entity using the following qualifier format:

"movies = %@", someMovieObj

The resulting qualifier returns no matches when evaluated in memory because the array property is not equal to the movie object as determined by **isEqual:**. However, when it's evaluated in the database, it returns the same studio N times

(where N is the number of movies in the Studio's movies array), even though the qualifier is attempting to match only one movie.

Workaround: Use the contains operator for qualifiers in-memory evaluation and the equality (=) operator (with **usesDistinct** on the fetch specification) for evaluation in the database.

Reference: 69934

Issue: EOQualifier needs a case insensitive 'like' operator that works both in memory and in SQL.

Workaround: You can use a pattern like '*[Hh][Ee][Ll][Ll][Oo]*' or you can create a method on the enterprise object that always returns a version in uppercase and use that method as a key in the qualifier.

Interface Layer

These issues exist in the interface layer of this Enterprise Objects Framework release:

Reference: 77378

Issue: Undo of uncommitted edit in text field doesn't undo.

Description: Make a change in a text field, and then, without exiting the field, press undo. The change that you made in the text field is not undone.

This is happening because the editing context only knows about changes to enterprise objects. An uncommitted edit in a text field is not known to the enterprise object and thus not to the editing context or undo manager. Consequently, it won't be undone.

Workaround: Users can leave the field (tab or hit return) and then undo.

To make this work correctly, you'd need to subclass the EOGenericControlAssociation to register an undo record with the undo manager in **control:textShouldBeginEditing:**. The association would need to be smart enough to know to ignore callbacks from the undo manager when it has already committed the edit (since at that point the edit would be undone by the editing context).

Reference: 71553

Issue: EOPickTextAssociation displays an alert panel whenever the '[' character is entered.

Description: EOPickTextAssociation should either escape all substitution characters or wait until a complete expression is typed in before executing. Since it does not, EOQualifier thinks that it has found an illegal pattern and raises an exception, which the EOPickTextAssociation displays in an alert panel.

Workaround: None.

Reference: 76902

Issue: Query by example does not work correctly for to-many relationship properties.

Description: If a query interface's user interface control is bound to a to-many relationship property (using the EODetailSelection association, for example) the resulting query searches on only the first object added to the to-many relationship array (instead of searching on all the objects in the array).

Workaround: Don't use Query By Example for to-many relationship properties<implement your own query mechanism instead.

Reference: 57842

Issue: An EODisplayGroup doesn't show its keys in Interface Builder's Inspector.

Description: This occurs when Enterprise Objects Framework is unable to find the model file for an EODisplayGroup's entity. To verify that this is the issue, inspect the EODisplayGroup's data source (click on the EODisplayGroup, open the Inspector panel, and select the DataSource panel from the Inspector popup). If the Model field is blank, then Enterprise Objects Framework is unable to find your model.

Workaround: Quit Interface Builder and verify that the model containing the entity referenced in the EODisplayGroup is added as a resource in the project containing the nib file.

Reference: 65061

Issue: Interface Builder connections are broken when you make changes to a model.

Description: When the name of an EOAttribute or EORelationship is changed in a model, any EOAssociations that use the old name become invalid because EOAssociations' keys aren't automatically updated to the new name. Unfortunately, Interface Builder's Connection Inspector doesn't directly support breaking the connection.

Workaround: To repair broken connections:

1. Select the display object that's bound to the obsolete key.
2. Use the associations popup to select "Outlets."
This removes the old association connectors.
3. Reselect the appropriate association type and reform the association to the new key.

Reference: 67804

Issue: EOModeler can't find model from another framework.

Description: This issue has two symptoms:
· When you load a nib file into your application, it can't find the model you have in your framework.
· When you save changes to a model file in your framework, the change isn't reflected in open nib files.

Enterprise Objects Framework 2.x finds models for an application by looking for all models in the application and in any frameworks used by the application. By default Enterprise Objects Framework looks for referenced framework in their *installation* location. Thus if you don't have the framework that contains the model installed, Enterprise Objects Framework won't find the model. Similarly, a change saved to a model in the framework project isn't noticed by Interface Builder since it's looking at the *installed* version, not the source version.

Workaround: You can tell Enterprise Objects Framework to look at the source for your framework projects by using the following defaults command (executed in a shell):

defaults write NSGlobalDomain EOProjectSourceSearchPath "($(HOME)/myProjectsDirectory1, /myOtherProjectsDirectory)"

Then, when Interface Builder or EOModeler is looking for models contained in one of your frameworks, it will first search all project directories within **$(HOME)/myProjectsDirectory1** and **/myOtherProjectsDirectory** before searching for the built versions.

Alternatively, if you update a model in a framework, reinstall the framework (via **make install**), restart Interface Builder, and reopen the application nib file.

Reference: 68604

Issue: Repeated false alert that Enterprise Objects Framework 1x nib file is being converted to Enterprise Objects Framework 2.0.

Description: When you reopen a nib file after conversion you get the message: ªThis Enterprise Objects Framework 1x nib file has been translated to Enterprise Objects Framework 2.0. If you did not intend to convert to Enterprise Objects

Framework 2.x, unload EOPalette, quit Interface Builder without saving this file, and reopen the nib.º

Workaround: Quit Interface Builder, then reopen the nib file.

Reference: 70847

Issue: After disconnecting all EOColumnAssociations from a table view, you can't reconnect the table view columns to a different EODisplayGroup.

Description: Suppose you form EOColumnAssociations between all of a table view's columns and an EODisplayGroup, and suppose you then disconnect them all. Subsequent attempts to connect a column to a different display group are not allowed. (All of the display group's properties are grayed out in Interface Builder's inspector.)

The reason for this is as follows. When the first EOColumnAssociation for a table view is created, an EOTableViewAssociation is also created and connected to the table view itself. The EOTableViewAssociation remains connected to the original display group even after all the columns have been disconnected, preventing columns from being connected to a different display group.

Workaround: To make the new connection, click on the table view and disconnect the EOTableViewAssociation.

Reference: 73688

Issue: EOPalette finds the wrong models for projects contained in another project's directory.

Description: When you open a nib whose project is in a subdirectory of another project, Interface Builder uses the model from the parent directory, instead of the model from the nib's own project.

Workaround: Do not store projects directly inside another project's directory. Instead, put at least one level of directories between the projects. For example, instead of putting "test" projects directly in a master project's directory, put them in a subdirectory called "Tests".

Reference: 74947

Issue: If you drag a symbolic link for a model into Interface Builder and answer YES to the "add Model to project" panel, Interface Builder crashes.

Workaround: Drag the actual model file instead of the symbolic link.

Reference: 76591

Issue: EOPalette tries to load model files twice in aggregate projects.

Description: Suppose you have an aggregate project that contains a framework for business logic (and associated model files) and that also contains an application that uses the business logic framework. If you try to open the application's nib file, Interface Builder tries to add the model file to the EOModelGroup twice, raising an exception. This occurs because Interface Builder finds the model in the aggregate project and then finds it again in the framework linked by the application (which is part of the aggregate).

Workaround: Don't keep your application and framework projects in the same aggregate project.

Reference: 76892

Issue: Multiple fetch-on-load display groups associated with an invalid connection dictionary can cause an exception.

Description: When loading a nib file that has more than one display group set to fetch on load, an application can crash if the display groups' model has an invalid connection dictionary. A crash occurs because the second display group tries to run the adaptor's login panel while the first one already has the panel open. This confuses the Application Kit.

Workaround: Validate the connection dictionaries for all models in the [EOModelGroup defaultGroup] before opening the nib.

Miscellaneous Framework

These issues exist in this Enterprise Objects Framework release:

Reference: 46679

Issue: Enterprise Objects Framework's private instance variables aren't declared **@private** and don't have names that begin with the underbar ('_') character.

Description: All instance variables in Enterprise Objects Framework should be considered private.

Workaround: Don't directly access Enterprise Objects Framework instance variables.

Reference: 69211

Issue: Link errors on Windows NT.

Description: Programs on Windows NT must add explicit references to at least one class in each framework in order to avoid link errors at run time.

Workaround: Add a function like that in the following code snippet, which refers to classes in each of Enterprise Objects Framework's layers. Though never invoked, it forces the appropriate linking to occur.

```
#ifdef WIN32
#import <EOControl/EOControl.h>
#import <EOAccess/EOAccess.h>
#import <EOInterface/EOInterface.h>

void _referenceAllEOFrameworks()
{
[EODisplayGroup new]; // EOInterface
[EOEntity new]; // EOAccess
[EOEditingContext new]; // EOControl
}
#endif
```

If you create your project with the type "EOApplication," this code is automatically added to your project main file.

Reference: 72027

Issue: EOKeyValueCoding is broken for doubles on HPUX PDO.

Description: EOKeyValueCoding doesn't work correctly for accessor methods that set and return doubles on HPUX under PDO 4.1 (and previous releases). This means that users cannot correctly fetch enterprise objects that have class properties with accessor methods that use doubles.

Workaround: Change your enterprise objects' accessor methods to return and take as arguments NSNumbers, NSDecimalNumbers, or **int**s.

Informix Adaptor

These issues exist in the Informix adaptor supplied with this release of Enterprise Objects Framework:

Reference: 64031

Issue: Informix adaptor user defaults for Enterprise Objects Framework 2.x are different than those for Enterprise Objects Framework 1.2.

Description: In Enterprise Objects Framework 1.2, the InformixAdaptor stores defaults in the EOFInformixAdaptor domain and uses the following keys:
INFORMIXDIR, DBDATE, DBLANG, DBMONEY, InformixLogErrors, ShowSystables, ShowTableOwner, Beautify, DefaultIsolationLevel, GlobalOptimization, GlobalExplain, GlobalLockMode, GlobalPDQPriority, GlobalDataSkip, GlobalConstraints, DatabaseExclusive

Enterprise Objects Framework 2.x stores defaults in the standard NSGlobalDomain and prefixes all keys with ªInformixº, that is:
InformixINFORMIXDIR, InformixDBDATE, InformixDBLANG, InformixDBMONEY, InformixLogErrors, InformixShowSystables, InformixShowTableOwner, InformixBeautify, InformixDefaultIsolationLevel, InformixGlobalOptimization, InformixGlobalExplain, InformixGlobalLockMode, InformixGlobalPDQPriority, InformixGlobalDataSkip, InformixGlobalConstraints, InformixDatabaseExclusive.

Workaround: None.

Reference: 70232

Issue: Informix adaptor raises an exception when you try to sort on attributes that are not in the select list.

Description: Due to a restriction in the Informix adaptor, it's not possible to sort on attributes that aren't included in the select list. This means that it isn't possible to sort the results using an attribute that is not marked on the entity as either a primary key, used for locking, or a class property.

Workaround: If possible, add the attribute to the entity and mark it as used for locking. Otherwise, there is no workaround.

Oracle Adaptor

These issues exist in the Oracle adaptor supplied with this release of Enterprise Objects Framework:

Reference: 78072

Issue: Using the "Set Adaptor Info" menu item in EOModeler to change the connection string results in a model that can't connect to the Oracle database.

Description: If you have a connection dictionary that includes both the "serverID" and "hostMachine" keys and you use the "Set Adaptor Info" menu item to set the "serverID" value to a something new, the old hostMachine key remains in your connection dictionary. Unfortunately, this remnant will lead the OracleEOAdaptor to construct a connection string of the form "T:<hostMachine>:<serverID>" rather than just using "<serverID>".

This is likely to happen when you configure the examples to use a local database.

Workaround: You can remove the "hostMachine" key from the connection dictionary using the EOModeler ConnectionDictionary Inspector. Select the root EOModel, and display the Inspector. You can then select the row with the "hostMachine" key and click "Remove" to clear it from the connection dictionary.

Reference: 77517

Issue: If you try to update an enterprise object with an attribute that maps to a LONG RAW column while using on-demand locking, you get the following exception:

"fetchObject -- EODatabaseChannel 0x12345678: attempt to
lock object that has out of date snapshot"

Description: It appears that the Oracle database sometimes returns wrong BLOB values when it's passed "SELECT ... <long-raw-column,... FOR UPDATE". So when the EODatabaseChannel attempts to acquire a lock on the row, the results of the SELECT don't match the results that were gotten on the last SELECT (without the FOR UPDATE clause).

Workaround: None. You can't use on-demand locking if you're going to be updating tables with LONG RAW columns.

Reference: 77366

Issue: If you're using pessimistic locking in combination with batch faulting or prefetching of relationships, you'll get the error "ORA-01786: FOR UPDATE of this query expression is not allowed" when you run your application.

Description: When you use pessimistic locking mode in combination with batch faulting or prefetching of relationships, Enterprise Objects Framework generates a SQL statement like the following:

<OracleSQLExpression: "SELECT DISTINCT t0.CATEGORY, t0.DATE_RELEASED, t0.LANGUAGE, t0.MOVIE_ID, t0.RATING, t0.REVENUE, t0.STUDIO_ID, t0.TITLE FROM DIRECTOR t1, MOVIE t0 WHERE t1.TALENT_ID = :talentID AND t0.MOVIE_ID = t1.MOVIE_ID FOR UPDATE" withBindings:{talentID = 87; }>

This statement fails with the ORA-01786 error. The Oracle RDBMS doesn't support the use of DISTINCT with the FOR UPDATE clause.

Workaround: If you use the pessimistic locking mode against an Oracle database, you can't use the batch faulting or prefetching features.

Reference: 62425

Issue: Oracle Adaptor doesn't read stored procedures inside of packages.

Description: There is no way to get the database to tell you the components (procedures and functions) that are inside a package definition. Clients can still create stored procedures in the model that will call into packages, it's just that model description using EOModeler won't create these at connect time.

Workaround: You can use EOModeler to create the stored procedure definitions in the model. Just set the external name of the stored procedure to *package-name.procedure-name*.

Reference: 63348

Issue: Converted models have no width information<Oracle fetches empty strings.

Description: The Enterprise Objects Framework 2.x Oracle Adaptor has issues if you attempt to use an eomodel file from the Enterprise Objects Framework 1.0 release. These model files don't contain width information for string values, which results in all the strings being fetched with 0 length. If this happens for the column that is the primary key, you will also have issues with uniquing since every row will appear to have the same key.

Workaround: Use EOModeler to add width information for VARCHAR2 and RAW columns.

Reference: 73333

Issue: The Oracle adaptor has character set issues on Sparc and m68k.

Description: The Oracle adaptor on Mach does not properly support certain character set conversion on certain architectures:

· On SPARC ISOLatin1 works, but Japanese character sets do not.
· On m68k non-ASCII ISOLatin1 characters are stripped and Japanese character sets don't work at all.

On Intel all character sets work fine, including European and Japanese.

Workaround: To get non-ASCII character sets on SPARC and m68k, install the **EO2JOracleAdaptor.pkg** that's on the Enterprise Objects Framework 2.1 Mach CD.

Note: The EO2J Oracle Adaptor is built with the 7.0 version of the Oracle client libraries. Consequently, returning fetch sets from stored procedures is not supported.

Sybase Adaptor

These issues exist in the Sybase adaptor supplied with this release of Enterprise Objects Framework:

Reference: 62634

Issue: The Sybase adaptor uses **CS_CONVERT()** to convert numeric data into NSDecimalNumbers.

Description: Fetching decimal numbers in locales that use a characters other than `.' for the decimal may not work.

Workaround: None.

Reference: 63169

Issue: Models created for version 4.9 Sybase servers do not include stored procedures.

Description: EOModeler gets stored procedure information using functionality that isn't provided in old servers.

Workaround: Use EOModeler's Stored Procedure Editor to add EOStoredProcedure objects to a model.

Reference: 75024

Issue: The SQL generation for primary key support in the Sybase adaptor isn't sufficient.

Description: The SQL generated by EOModeler to support primary key generation in Sybase simply invokes the **sp_primarykey** stored procedure. **sp_primarykey** adds useful information to the syskeys table, but doesn't create constraints that enforce uniqueness (or NOT NULL) in the primary key columns.

Workaround: Add the constraints yourself using statements of the following form:

alter table <table-name> add constraint primary key (<column-name> {, <column-name })

EOModeler

These issues exist in EOModeler with this release of Enterprise Objects Framework:

Reference: 78497

Issue: If you try to save a 1.x **.eomodel** file in 2.1, you get the following error:

Apr 18 16:50:23 EOModeler[377] Unable to write file ~/projects/foo.eomodel/DiagramLayout

Description: In Enterprise Objects Framework 1.1, the model file was stored in one large property list file. When model files were put into a directory structure for 2.0, EOModeler was designed to open both **.eomodel** and **.eomodeld** model files. In 2.x releases EOModeler writes out any **.eomodel** file as one file.

The issue is that when you save models, the code in the Diagram View that saves layout information attempts to write into an **.eomodeld** directory. If it doesn't find one, it raises an exception.

This error can also occur if you perform a Save As operation and actually enter a name that ends in **.eomodel**.

The good news it that the Save of the file actually completes successfully, so any changes you made will not be lost. EOModeler is left in a potentially unstable state, but you can safely quit and restart it and the model will be fine.

Workaround: If you encounter this error, quit EOModeler and reopen the file. Choose "Save As" and provide a file name that ends in an **.eomodeld** extension.

Reference: 78222

Issue: In diagram mode in EOModeler, dragging around an entity that is being edited can lead to strange behavior and exceptions.

Workaround: Finish editing before moving the entity.

Reference: 77880

Issue: EOModeler exhibits odd behavior if you try to paste model objects from a closed window.

Description: Copy a model object (or objects), close the window from which you copied, and then open a new window. The Paste menu item is enabled in the new window, but if you try to paste, nothing happens.

Workaround: Don't close the original window before pasting the model objects.

Reference: 77608

Issue: Existing Enterprise Objects Framework projects don't see the new Enterprise Objects Framework 2.1 source code generation templates (used when you issue the "Generate Source Files..." command in EOModeler).

Description: Enterprise Objects Framework 2.1 includes fixes and additions to EOInterfaceFile.template and EOImplementationFile.template. If a user has a project from Enterprise Objects Framework 2.0 that contains the old versions of these files, the old versions will continue to be used.

Workaround: If you didn't customize the templates, then you should just remove thes old files from your project.

If want to build a customized template based on the newest versions, copy
/NextDeveloper/Apps/EOModeler.app/Resources/EOImplementationFile.template and
/NextDeveloper/Apps/EOModeler.app/Resources/EOInterfaceFile.template into your project directory.

Reference: 77603

Issue: When you create a subclass in your model and generate source files for it, the resulting header file won't compile.

Description: For example, suppose you create a Salesman subclass of Employee and generate source files for it. The header for Salesman correctly inherits from Employee, but it doesn't include the **Employee.h** header, so it can't be compiled.

```
// Salesman.h
//
// Created on Mon Mar 10 10:19:41 PST 1997 by NeXT EOModeler Version 304

#import <EOControl/EOControl.h>

@class Employee;
@class Department;

@interface Salesman : Employee <NSCoding>
{
}

@end
```

If you attempt to compile this code, you'll get this error:

```
Salesman.h:12: Cannot find interface declaration for `Employee', superclass of `Salesman'
gnumake: *** [Salesman.o] Error 1
```

Workaround: Change
`@class Employee`
to

#import "Employee.h"

Reference: 77134

Issue: If you open two different Diagram View windows for the same model file, the layout for only one of the windows is saved, and which layout is saved is indeterminate.

Workaround: Only open one Diagram View window for a model at a time.

Reference: 77191

Issue: Pasted attributes do not retain their primary key, used for locking, or class property settings.

Description: If you copy and paste an attribute, the pasted attribute's primary key, used for locking, and class property bits revert to their default settings, regardless of their state in the original. This occurs because the settings are actually maintained by the owning entity, which isn't incorporated into an attribute's pasteboard rendering.

Workaround: Manually set the bits after pasting.

Reference: 51250

Issue: You can't join on derived attributes.

Description: Invalid SQL is generated whenever a derived attribute is designated as a join attribute in a relationship.

Workaround: None.

Reference: 75801

Issue: Editing nested dictionaries with the UserInfo or ConnectionDictionary editors doesn't work.

Description: Suppose that a model has a userInfo or connection dictionary that contains another dictionary. If you use EOModeler's UserInfo or Connection Dictionary Inspector to edit the enclosed object, EOModeler converts it to a string. For example, if the userInfo dictionary contains the following dictionary:

```
myValue = {
hello = world;
}
```

and you convert "hello" and "world" to uppercase, EOModeler saves the following string to the model file:

myValue = "{\\n HELLO = WORLD;\\n}"

Similarly, EOModeler converts arrays to strings.

Workaround: If you need to store such compound data structures in your userInfo or connectionDictionary, you will need to edit it by hand using Edit, or write a your own custom Inspector.

Wizard

These issues exist in the Wizard with this release of Enterprise Objects Framework:

Reference: 77987

Issue: The Wizard for creating new EOApplications can't use models that are accessed through symbolic links

Description: In Project Builder, if you attempt to create a new EOApplication that requires an EOModel and you specify a symbolic link to an EOModel, you will get the following error:

"write: Cannot create directory <project-location>/<model-name>"

Workaround: Specify a path that doesn't include a symbolic link.

On-line Examples

These issues exist in the on-line examples included in this release of Enterprise Objects Framework:

Reference: 78215

Issue: The UsingStoredProcedures example doesn't work for Sybase or Oracle

Description: For Oracle, the insertMovie and deleteMovie stored procedures have arguments with bad columnNames. For Sybase, the nextPrimaryKey and fetchMovieWithPrimaryKey stored procedures have arguments with bad column names.

Workaround: You can either change the names of the arguments in the stored procedure definition (by editing **oraclesp.sql** or **sybasesp.sql**), or you can change the columnName of the problematic arguments. Here is a detailed list of the changes you need to make in EOModeler to the columnNames to make the EOModel stored procedures match those in the database:

OracleStoredProcedures.eomodeld/deleteMovie.storedProcedure
movieID
AMOVIE_ID => MOVIE_ID
OracleStoredProcedures.eomodeld/insert.storedProcedure
category
ACATEGORY => CATEGORY
dateReleased
ADATE_RELEASED => DATERELEASED
language
ALANGUAGE => LANGUAGE
movieID
AMOVIE_ID => MOVIE_ID
rating
ARATING => RATING
revenue
AREVENUE => REVENUE
studioId
ASTUDIO_ID => STUDIO_ID
title
ATITLE => TITLE
SybaseStoredProcedures.eomodeld/fetchMovieWithPrimaryKey.storedProcedure
name
MOVIE_ID => movie_id
SybaseStoredProcedures.eomodeld/nextMoviePrimaryKey.storedProcedure
name
MOVIE_ID => A_MOVIE_ID

Reference: 77990

Issue: Sometimes when you run the **install_database** script or use the schema object creation window in EOModeler, you might get one of the following errors.

Mar 27 10:19:34 eoutil[1577] Exception running dump: ORA-00955: name is already used by an existing object
create table !!! eo_temp_table as select max(MOVIE_ID) counter from MOVIE

Mar 27 10:27:54 eoutil[1591] Exception running dump: ORA-00955: name is already used by an existing object
create procedure !!! eo_set_sequence is
xxx number;
yyy number;
begin
select max(counter) into xxx from eo_temp_table;
if xxx is not NULL then
yyy := 0;
while (yyy < xxx) loop
select MOVIE_SEQ.nextval into yyy from dual;

```
end loop;
end if;
end;
```

Description: If the primary key support code dies unexpectedly, it can leave the **eo_set_sequence** stored procedure and the **eo_temp_table** table in the user's schema. This isn't an issue right away, but any subsequent attempt to run the **install_database** script will fail because the statements that attempt to create these schema objects will fail and the data loading will stop before it is finished.

Workaround: Use the following commands from SQLPlus to remove these objects before you attempt to create the schema objects with the **install_database** script.

```
SQL> drop table eo_temp_table;
SQL> drop procedure eo_set_sequence;
```

Reference: 64283

Issue: Enterprise Objects Framework 2.x examples merge with obsolete Enterprise Objects Framework 1.1 examples.

Description: If a system has Enterprise Objects Framework 1.1 Developer installed on it (EODeveloper.pkg) and then upgrades to 4.0, the EODeveloper package (incorrectly) stays installed, and the examples stay in **/NextDeveloper/Examples/EnterpriseObjects**.

When the user later installs EO2Developer, the Enterprise Objects Framework 2.x examples are merged with the Enterprise Objects Framework 1.1 example files already in **/NextDeveloper/Examples/EnterpriseObjects**.

Workaround: Uninstall 1.1 EODeveloper.pkg before installing EO2Developer.pkg.

Reference: 65165

Issue: **install_database** doesn't work: Sybase: Can't find type `decimal'.

Description: The **install_database** script in the **EnterpriseObjects/DatabaseSetUp** directory doesn't work for Sybase 4.9 servers.

When the models in the examples directory were converted to Sybase, the server version wasn't taken into account. Some of the attributes were converted to ªdecimalº data type and the Sybase 4.x server doesn't know about these.

Workaround: Use EOModeler to find and change all the external types from decimal to float in each of the models in your examples directory.

Reference: 68231

Issue: **make all** in the Enterprise Objects Framework examples fails sometimes.

Description: The Enterprise Objects Framework examples will fail to make if **${NEXT_ROOT}/LocalDeveloper** is present on your system and you don't have write access to it. The makefile tries to install the BusinessLogic framework in the **/LocalDeveloper/Frameworks** directory.

Workaround: Execute **make** as root or ask your system administrator to create a **/LocalDeveloper/Frameworks** directory and make it writable by you.

Reference: 70557

Issue: The Customer.app example doesn't propagate changes to CreditCard objects.

Description: The relationship between CreditCard and Member is not modeled correctly in the examples. CreditCard's primary key is composed of its **cardNumber** and **cardType** attributes. In the Customer application, you can modify the **cardNumber** and **cardType** of a Member's CreditCard, but these changes aren't propagated to the objects to which the

CreditCard is related. That is, after saving the changes to the database, the CreditCard's **cardNumber** and **cardType** are updated, but foreign keys in the MEMBER table still have the old values.

CreditCard should have a separate primary key identifier, such as **cardID**, on which the CreditCard-Member relationships are based. This approach would keep CreditCards and Members in sync, and it would also be a more efficient implementation.

Workaround: None.

Reference: 72246

Issue: The ODBC adaptor source code provided as an example is only available on OpenStep for Windows NT.

Description: The source code for the ODBC adaptor is available on Windows NT as an example. It is not, however, included on Mach or PDO.

Workaround: Copy the source code from an NT machine.

Note: If you just want the ODBC adaptor to see an example of a concrete adaptor, you can look at the FlatFile adaptor that's included in all releases.

Reference: 76020

Issue: In the Studios.app, buying the movies associated with a Talent doesn't update the Movies' Studios.

Description: The Studio class's **buyAllMoviesStarring:** method doesn't take advantage of Enterprise Objects Framework's EOKeyRelationshipManipulation methods. Instead, it simply invokes [self addToMovies:...].

Workaround: Change **Studio.m**'s **buyAllMoviesStarring:** implementation to the following:

```
- (void)buyAllMoviesStarring:(Talent *)talent
{
NSEnumerator *movieEnumerator = [[talent moviesStarredIn] objectEnumerator];
id movie;

while ( (movie = [movieEnumerator nextObject]))
[self addObject:movie toBothSidesOfRelationshipWithKey:@"movies"];
}
```

Reference: 69419

Issue: Example data for Movie and Rental models must be installed in different databases.

Description: When installing data for more than one model in a database, the **eo_sequence_table** is only properly initialized for the first model installed.

Workaround: You can either install the data for each model in a different database or change the last line in the **install_database** script located in the DatabaseSetUp directory of your examples directory as follows:

Change this:

${EOUTIL} dump ../BusinessLogic/Rentals.eomodeld -source plist database -schemaCreate -postInstall < RentalData.plist

To this:

${EOUTIL} dump ../BusinessLogic/Rentals.eomodeld -source plist database -schemaCreate -postInstall -force < RentalData.plist

When you use the **-force** option as a workaround, exceptions are logged because the **eo_sequence_table** table and

eo_pk_for_table procedure already exist when you execute **install_databases**. You can just ignore these exceptions.

Documentation

This issue exists in the documentation included in this release of Enterprise Objects Framework:

Reference: 77170

Issue: Enterprise Objects Framework Developer's Guide sections about ordering database operations are out of date.

Description: The sections "How Do I Order Database Operations" and "Constraints for Enforcing Relational Integrity Rules" in the chapter "Answers to Common Design Questions" in the Enterprise Objects Framework Developer's Guide need to be updated to reflect a new operation ordering algorithm.

The new algorithm works as follows:

· If an entity (Movie) has a to-one relationship to a second entity (Studio) and the inverse relationship is a to-many, then the second entity (Studio) is considered the *master*.
· If an entity (Talent) has a to-one relationship to a second entity (TalentPhoto) and the inverse relationship is also a to-one, then the entities are peers.

Enterprise Objects Framework builds up an entity ordering based on the "master-ness" of the entities. This ordering is built up dynamically and is enhanced as your application touches more and more entities.

Before sending operations to the database, Enterprise Objects Framework orders the operations based on the entity ordering. For inserts, Enterprise Objects Framework orders master entities first; whereas for deletes, Enterprise Objects Framework orders master entities last. Order on updates doesn't generally matter, Enterprise Objects Framework orders masters first.

This new algorithm should reduce the number of scenarios in which you have to reorder operations. However, if your database has sophisticated referential integrity, if it uses triggers, or there are referential integrity constraints that are not modeled as EORelationships, you may still need to reorder adaptor operations programmatically.

Macintosh 8■24 GC Card: QuickDraw Printer Problem (11/94)

I'm having problems printing from a Macintosh II with a Macintosh Display Card 8*24 GC connected to a LaserWriter SC. When acceleration on the Macintosh Display Card 8*24 GC is on, QuickDraw fill patterns aren't printing properly. I am running System 6.0.5 with LaserWriter SC driver 1.1.

If I turn off acceleration on the Macintosh Display Card 8*24 GC and restart, everything works fine. But restarting each time I want to print is not a satisfactory solution.

This article has been archived and is no longer updated by Apple.
After doing some testing, we discovered that this problem happens with any of Apple's QuickDraw printers. We have told Engineering about the problem and will announce a solution when we have it.

In the mean time, we suggest that you switch off the Macintosh Display Card 8*24 GC's acceleration before printing. You can do this using the card's Control Panel without rebooting or even quitting from an open application. We realize that this isn't a solution, but it is an adequate temporary workaround.

Third Party Driver: Ensoniq Soundscape OPENSTEP Driver Overview

This article discusses a third-party device driver for the OPENSTEP Mach operating system, versions 4.0 through 4.2. This driver is not produced, distributed or supported by Apple Computer.
This article has been archived and is no longer updated by Apple.
Driver: ENSONIQ Soundscape
Last Update: July 12, 1997

Availability Information

All versions of this driver are available only from Sound Consulting directly. This driver is not produced, distributed or supported by Apple Computer.

Latest Release Driver version: Version 3.35, order from Sound Consulting at SS_NSI@Sounds.wa.com
Latest Beta Driver version: Version 3.36, contact Sound Consulting for availability

Driver Name / Installer .pkg: EnsoniqSoundscape
Driver Type: Sound (Audio & MIDI)
Driver Scope: Product Family (including OEM and third-party compatibles)
Supported Components: ENSONIQ, Gateway, NEC, Reveal, Spea
PC Bus / Interface Supported by Driver*: ISA and PnP

General Overview notes: This driver is intended to support all Soundscape cards and compatible implementations based on the ENSONIQ chip set. Cards shipped in Gateway systems are supported as well.

Supported Products / Add-on Adaptors:
ENSONIQ Soundscape (ISA)
ENSONIQ SoundscapeELITE (ISA)
ENSONIQ SoundscapeVIVO 90 (PnP)
Gateway Soundscape 2, 2000, & SS2000 (ISA)
Gateway Soundscape - OPUS based (ISA)
Gateway Soundscape Revision 0, Revision 1, et al (PnP)
Gateway SoundscapeOFFICE (PnP)
Gateway SoundscapeVIVO (PnP)
NEC Harmony (PnP)
Spea Media FX 16 (ISA)
Reveal SC-600 (ISA)

Supported Products / Systems (i.e. integrated into PC System):
Gateway Soundscape (integrated as bus card shipped with system) (ISA & PnP)

Special Features of Driver / Driver Notes:
The Soundscape wave table based MIDI synthesizer is supported on all cards which can execute ENSONIQ OTTO firmware. The driver works in conjunction with the MusicKit Mididriver to enable MIDI on the Soundscape card.

Caveats: All Soundscape interrupts will not be available with the standard MusicKit Mididriver. An update package is available from Sound Consulting which replaces the (human readable) configuration files in the Mididriver so that all Soundscape interrupt settings are available.

This device driver provides information in the Configure application's help panel. Choose Info>Help from the Configure menu and scroll down to find this driver's help topic.

There are many models of Soundscape cards and they have different mixing capabilities. Gateway cards have special internal connectors for modem audio which can be mixed in. Mixing of line-in and CD audio is supported by an external application or Preferences bundle.

Sound Driver Details

Supported Connectors*: 1/8" Microphone In, 1/8" Stereo Line In, 1/8" Stereo Speaker Out, CD-ROM Stereo Line In, TV Stereo Line In, Modem Mono Line In
Access Mode: DMA
Adapter Memory: N/A
Attributes: 16-bit Linear, 8-bit Linear, 8-bit mu-Law & A-Law

Known Problems
The are no known driver problems.

In order to configure resources (like IRQ, DMA, I/O Port Addresses) correctly, make sure that the system BIOS knows about the resources used by this and other ISA adaptors.

Use the PnP personality for Soundscape PnP boards and enable support for Plug-and-Play in the EISABus driver (if you are using the driver from NeXTanswers).

Driver Version Notes

3.30 - Initial release, 1st quarter, 1996
3.31 - Added more Help information and update the PnP personality tables, November 1996
3.32 - Support SoundscapeVIVO introduced at Apple WWDC, May 1997
3.33 - Demo created with limited abilities and timeout, June 1997
3.34 - Minor VIVO 90 enhancements, July 1997
3.35 - Currently shipping licensed version, July 1997
3.36 - Enhanced license keys, January 1998

Future Planning

Future / Update Planning: SoundscapeVIVO and VIVO 90 wavetable support
Reason for New Driver / Update: Newest VIVO cards do not support on-board synthesis, only external
New Driver / Update Timeframe: 4th quarter, 1998

New Driver / Update Description:
The new SoundscapeVIVO from Gateway and VIVO 90 from ENSONIQ have a reduced chip count and lower price, but are not compatible with the on-board synthesis support in the shipping driver. ENSONIQ have provided Sound Consulting with two models of the VIVO card along with engineering documentation and development is under way.

The first public release of Rhapsody will also be supported for all sound cards listed above.

Note: Information contained in the "Future Planning" section of this document does not constitute a commitment on the part of Sound Consulting to complete the planned development work.

* - Indicates information that is inclusive of the entire capability of this driver. Not all devices supported by this driver may include all features listed. Check any available NeXTanswers or the hardware manual for the device for additional information.

EOF 2.0 Multiple BLOB Problem Workaround

This article describes a workaround for a problem with Enterprise Objects Framework version 2.0. This problem has been fixed in EOF 2.1 and later versions.

The WebObjects Current Patch List, **TIL article 70037**, contains information on all available patches and workarounds for all versions of WebObjects, including EOF patches. The OPENSTEP Current Patch List, **TIL article 70033**, contains information on all available patches and workarounds for all versions of OPENSTEP, including EOF patches. Please read these documents if you're not sure which patches you need on your system.

This article has been archived and is no longer updated by Apple.
The Multiple BLOB workaround example code is available from:

ftp://ftp.info.apple.com/Apple_Support_Area/Apple_Software_Updates/MultiCountry/Enterprise/EOF/patches/2.0/Multiple_BLOB.compressed

Published Date: Feb 20, 2012

NeXTSTEP 3.3 Driver: 3COM EtherLink XL

This document discusses a device driver for the NeXTSTEP operating system, version 3.3. This driver will not work with any version of OPENSTEP.
This article has been archived and is no longer updated by Apple.

Availability Information

An updated BETA version of this driver, version 3.32, is avaiable on Apple's FTP servers at:
ftp://ftp.info.apple.com/Apple_Support_Area/Apple_Software_Updates/MultiCountry/Enterprise/nextstep/drivers/beta/EtherLinkXL.pkg.compressed

Driver Name / Installer .pkg: EtherLinkXL
Driver Type: Networking
Driver Scope: Product Family
Supported Components:
PC Bus / Interface Supported by Driver:** PCI

General Overview notes: This driver supports the 3Com EtherLink XL family of PCI Ethernet Adapters.

Supported Products / Add-on Adapters:
3Com EtherLink XL 3C900-TPO PCI (RJ-45)
3Com EtherLink XL 3C900-Combo PCI (BNC, AUI, RJ-45)
3Com EtherLink XL 3C905-TX PCI (10Base-T, 100Base-TX)
3Com EtherLink XL 3C905B-TX PCI (10Base-T, 100Base-TX)

Supported Products / Systems (ie integrated into PC System):

Special Features of Driver / Driver Notes:
3C905-TX cards identified with ASSY 03-0104-001 REV A may experience large number of receive errors and transmit timeouts. There is no workaround to this problem.

Networking Driver Details

Network Type:** 100 Base TX, EtherNet, Full Duplex
Speed*: 10 Mb/s, 100 Mb/s
Access Mode:** Bus Master DMA
Buffer Size*: 8KB
Supported Connectors:** AUI, BNC (10Base-2), RJ-45 (10Base-T)

Known Problems

Driver Version Notes

3.30 - Initial beta version
3.32 - Added support for 3C90xB adapter family. Single personality to handle all cards. Better media detection algorithm, and supports Nway auto-negotiation.

** - Indicates information that is inclusive of the entire capability of this driver. Not all devices supported by this driver may include all features listed. Check any available NeXTanswers and the hardware manual for the device for additional information.

3Com EtherLink XL OPENSTEP Driver Overview

This article discusses a device driver for the OPENSTEP Mach operating system, versions 4.0 through 4.2.
This article has been archived and is no longer updated by Apple.
Driver: 3COM EtherLink XL
Last Update: January 25, 1999

Availability Information

An updated release version of this driver, version 4.02, is avaiable on Apple's FTP servers at:
ftp://ftp.info.apple.com/Apple_Support_Area/Apple_Software_Updates/MultiCountry/Enterprise/openstep/drivers/released/EtherLinkXL.pkg.compressed
An updated BETA version of this driver, version 4.03, is avaiable on Apple's FTP servers at:
ftp://ftp.info.apple.com/Apple_Support_Area/Apple_Software_Updates/MultiCountry/Enterprise/openstep/drivers/beta/EtherLinkXL.pkg.compressed

Driver Name / Installer .pkg: EtherLinkXL
Driver Type: Networking
Driver Scope: Product Family
Supported Components:
PC Bus / Interface Supported by Driver*: PCI

General Overview notes: This driver supports the 3Com EtherLink XL family of PCI Ethernet Adapters.

Supported Products / Add-on Adapters:
3Com EtherLink XL 3C900-TPO PCI (RJ-45)
3Com EtherLink XL 3C900-Combo PCI (BNC, AUI, RJ-45)
3Com EtherLink XL 3C905-TX PCI (10Base-T, 100Base-TX)
3Com EtherLink XL 3C905B-TX PCI (10Base-T, 100Base-TX)

Supported Products / Systems:
Dell Optiplex GX/1 onboard 3C905B Ethernet controller

Special Features of Driver / Driver Notes:
3C905-TX cards identified with ASSY 03-0104-001 REV A may experience large number of receive errors and transmit timeouts. There is no workaround to this problem.

Networking Driver Details

Network Type*: 100 Base TX, EtherNet, Full Duplex
Speed*: 10 Mb/s, 100 Mb/s
Access Mode*: Bus Master DMA
Buffer Size*: 8KB
Supported Connectors*: AUI, BNC (10Base-2), RJ-45 (10Base-T)

Driver Version Notes

4.00 - Initial beta version
4.02 - Added support for 3C90xB adapter family. Single personality to handle all cards. Better media detection algorithm, and supports Nway auto-negotiation.
4.02 - Added support for Dell Optiplex GX/1 onboard 3C905B Ethernet controller

* - Indicates information that is inclusive of the entire capability of this driver. Not all devices supported by this driver may include all features listed.

Number Nine Imagine128 Series 2 OPENSTEP Driver Overview

This article discusses a device driver for the OPENSTEP Mach operating system, versions 4.0 through 4.2.
This article has been archived and is no longer updated by Apple.
Driver: Number Nine Imagine128 Series 2
Last Update: December 18, 1997

Availability Information

An updated release version of this driver, version 4.02, is avaiable on Apple's FTP servers at:
ftp://ftp.info.apple.com/Apple_Support_Area/Apple_Software_Updates/MultiCountry/Enterprise/openstep/drivers/released/Num9Imagine128S2.pkg.compressed

Driver Name / Installer .pkg: Number9Imagine128S2DisplayDriver
Driver Type: Display
Driver Scope: Product Family
Supported Components: IBM RGB 526 RAMDAC, IBM RGB 528 RAMDAC, Number9 Imagine II, Number9 T2R
PC Bus / Interface Supported by Driver:** PCI

General Overview notes: This graphics driver is designed to support the Imagine 128 Series 2 and Revolution 3D adapters from Number Nine Visual Technology Inc.

This driver supports the use of 4MB, or 8MB of display memory. This driver also includes support for multi-headed displays.

Supported Products / Add-on Adapters:
Number9 Imagine 128 Series 2 (4MB) (90-228120-000)
Number9 Imagine 128 Series 2 (8MB) (90-228130)
Number9 Revolution 3D (4MB)
Number9 Revolution 3D (8MB)

Special Features of Driver / Driver Notes:
This device driver provides information in the Configure application's help panel. Choose Info>Help from the Configure menu and scroll down to find this device driver's help topic.

Display Driver Details

Supported Connectors: 15-pin High Density (VGA)
Access Mode: Linear Framebuffer
Adapter Memory: 4MB VRAM, 4MB WRAM, 8MB VRAM, 8MB WRAM

Display Modes (Number in () after resolution indicates frame buffer size required)

32 Bit Color Modes*:
1024x768 (4MB+), 1152x864 (4MB+), 1600x1200(8MB+), 640x480 (2MB+), 800x600 (2MB+)

16 Bit Color Modes*:
1024x768 (2MB+), 1152x864 (2MB+), 1280x1024 (4MB+), 1600x1200 (4MB+), 640x480 (1MB+), 800x600 (1MB+)

8 Bit Color / Greyscale Modes*:
1024x768 (1MB+), 1152X864 (1MB+), 1280x1024 (2MB+), 1600x1200 (4MB+), 640X480 (1MB+), 800x600 (1MB+)

Known Problems

Some PCI machines will not start up if there is more than one Number Nine Imagine128 display adpter present. This is a BIOS limitation.

The Revolution 3D cards used for driver development exhibited a slight distortion on screen under the following display modes:

1600x1200x32@70Hz
1280x1024x32@75Hz

The distortion causes the right side of windows to undulate. This is most noticeable on a text filled window with white background. This seems to be caused by some unknown hardware problem on those cards.

Driver Version Notes

4.00 - Initial Version
4.01 - Added support for Series 2 cards with integrated VGA controller. Added support for 8MB VRAM cards.
4.02 - Added support for Revolution 3D cards based on the T2R engine and WRAM display memory.

* - Indicates information that is inclusive of the entire capability of this driver. Not all devices supported by this driver may include all features listed.

NeXTSTEP 3.3 Driver: DECChip 21X4X Networking

This document discusses a device driver for the NeXTSTEP operating system, version 3.3. This driver will not work with any version of OPENSTEP.
This article has been archived and is no longer updated by Apple.

Availability Information

An updated BETA version of this driver, version 3.31, is avaiable on Apple's FTP servers at:
ftp://ftp.info.apple.com/Apple_Support_Area/Apple_Software_Updates/MultiCountry/Enterprise/nextstep/drivers/beta/DECChip21x4xNet.pkg.compressed

Driver Name / Installer .pkg: DEC21X4XNetwork
Driver Type: Networking
Driver Scope: Specific Product
Supported Components: DEC DECchip21040, DEC DECchip21041, DEC DECchip21140, DEC DECchip21142, DEC DECchip21143
PC Bus / Interface Supported by Driver:** PCI

General Overview notes: This driver supports PCI-bus network adapters or on-board network adapters based on DECchip 21X4X LAN Controller. This includes the 21040, 21041, 21140, 21142, and 21143 LAN Controllers. Both 10Mb/s and 100Mb/s connection speeds are supported.

Supported Products / Add-on Adapters:
Adaptec-Cogent ANA-6911A/TX
Cogent EM110-TX Fast Ethernet 10/100 Adapter
Cogent EM960 PCI
DEC DE500 (21143 based) PCI 10/100
DEC DE500 Fast EtherWORKS PCI 10/100
DANPEX PCI Ethernet (EN-9400P3)
SMC 9332 Fast Ethernet 10/100 Adapter
SMC PCI EtherPower (SMC 8432)

Supported Products / Systems (ie integrated into PC System):
DEC Celebris GL On-Board LAN Adapter (21142/21143, 10 Mb/s module)
DEC Celebris GL On-Board LAN Adapter (21142/21143, 10/100 Mb/s module)

Special Features of Driver / Driver Notes:
This device driver provides information in the Configure application's help panel. Choose Info>Help from the Configure menu and scroll down to find this device driver's help topic.

Networking Driver Details

Network Type:** 100 Base FX, 100 Base T4, 100 Base TX, EtherNet, Full Duplex
Speed*: 10 Mb/s, 100 Mb/s
Access Mode:** Bus Master DMA
Buffer Size*: NA
Supported Connectors:** AUI, BNC, UTP

Known Problems

Due to ongoing development and testing of OPENSTEP 4.0, the beta version (v3.30) of this driver will neither be tested on NEXTSTEP 3.3 nor upgraded to "Released" status.

Driver Version Notes

3.30 - Initial release
3.31 - Fixed a SROM parsing bug which prevented the driver from working with the ANA-6911A/TX cards.

** - Indicates information that is inclusive of the entire capability of this driver. Not all devices supported by this driver may include all features listed. Check any available NeXTanswers and the hardware manual for the device for additional information.

ATI Rage OPENSTEP Driver Overview

This article discusses a device driver for the OPENSTEP Mach operating system, versions 4.0 through 4.2.
This article has been archived and is no longer updated by Apple.
Driver: ATI Rage
Last Update: June 16, 1998

Availability Information

A version of this driver is on the OPENSTEP CD-ROM
An updated release version of this driver, version 4.03, is avaiable on Apple's FTP servers at:
ftp://ftp.info.apple.com/Apple_Support_Area/Apple_Software_Updates/MultiCountry/Enterprise/openstep/drivers/released/ATIRage.pkg.compressed
An updated BETA version of this driver, version 4.04, is avaiable on Apple's FTP servers at:
ftp://ftp.info.apple.com/Apple_Support_Area/Apple_Software_Updates/MultiCountry/Enterprise/openstep/drivers/beta/ATIRage.pkg.compressed

Driver Name / Installer .pkg: ATIRageDisplayDriver
Driver Type: Display
Driver Scope: Generic-Chipset
Supported Components: ATI 3D Rage, ATI 3D Rage II, ATI 3D Rage II+, ATI 3D Rage Pro
PC Bus / Interface Supported by Driver*: AGP, Integrated, PCI

General Overview notes: This new graphics driver is designed to support a variety of graphics adapters based on the ATI Rage, Rage II, and Rage Pro graphics controllers. This driver supports a variety of configurations including high-resolution and high-color (32bit) modes and several frame buffer configurations.

Due to the wide range of possible combinations, only a few specific adapters were tested by Apple. Although this driver may work with most 88800 GX/CX based adapters, Apple will only support the specific adapters tested by Apple.

Supported Products / Add-on Adapters:
ATI All-In-Wonder
ATI 3D Pro Turbo
ATI 3D Pro Turbo PC2TV
ATI 3D Xpression+
ATI 3D Xpression+ PC2TV
ATI XPERT @ Work
ATI XPERT @ Play

Supported Products / Integrated:

Dell Optiplex GX1 (ATI Rage Pro AGP on-board) (requires driver version 4.04)

Special Features of Driver / Driver Notes:
Version 4.04 adds support the Rage card's on-board AGP implementation. This device driver provides information in the Configure application's help panel. Choose Info>Help from the Configure menu and scroll down to find this device driver's help topic.

Display Driver Details

Supported Connectors: 15-pin High Density (VGA)
Access Mode: Linear Framebuffer
Adapter Memory: 2MB DRAM, 2MB VRAM, 4MB DRAM, 4MB VRAM, 6MB VRAM, 8MB VRAM

Display Modes (Number in () after resolution indicates frame buffer size required)

32 Bit Color Modes*:
1152x900 (4MB+), 1280x1024(4MB+), 1600x1200(8MB+), 640x480 (4MB+), 800x600 (4MB+)

16 Bit Color Modes*:
1024x768 (2MB+), 1152x896 (2MB+), 1280x1024 (4MB+), 1600x1200 (4MB+), 640x480 (1MB+), 800x600 (1MB+)

8 Bit Color / Greyscale Modes*:
1024x768 (1MB+), 1152x896 (1MB+), 1280x1024 (2MB+), 1600x1200 (2MB+), 640X480 (1MB+), 800x600 (1MB+)

* - Indicates information that is inclusive of the entire capability of this driver. Not all devices supported by this driver may include all features listed.

Sybase DBKit Adaptor Compatability Patch

This patch solves a backward compatibility problem in OPENSTEP 4.x where DBKit applications give the following error when using the Sybase DBKit adaptor.

Error loading /NextLibrary/Adaptors/SybaseAdaptor.adaptor/SybaseAdaptor
rld(): Undefined symbols:
dyld_stub_binding_helper

The patch is a quad fat (m68k, Intel, HPPA, SPARC) copy of the NEXTSTEP 3.3 Sybase DBKit adaptor.

The OPENSTEP Current Patch List, **TIL article 70033**, contains information on all available patches and workarounds for all versions of OPENSTEP, including EOF patches. Please read this document if you're not sure which patches you need on your system.
This article has been archived and is no longer updated by Apple.
You can download the patch from:
ftp://ftp.next.com/pub/NeXTanswers/Files/Patches/SybaseDBKitAdaptorPatch/2548_SybaseDBKitAdaptorPatch.pkg.compressed

Installing the Sybase DBKit Adaptor Patch

Follow these instructions to install the *Sybase DBKit Adaptor Patch.*

1. Download the patch from Apple's FTP servers at:

ftp://ftp.info.apple.com/Apple_Support_Area/Apple_Software_Updates/MultiCountry/Enterprise/openstep/patches/SybaseDBKitPatch.compressed

2. Log in as **root**. (If you're not sure how to log in as **root**, see your system administrator.)

3. Make sure your computer is running *OPENSTEP Release 4.x*. (You can find the OPENSTEP version number with the Workspace Manager application's Info Panel command.)

4. Double-click the **SybaseDBKitAdaptorPatch.pkg** file.

5. Click the Install button in the Installer package window. An Install Package panel opens. Use this panel to select the same architecture and languages as you did when originally installing the *OPENSTEP 4.x User* software.

6. Click Install in the Install Package panel, and if prompted for confirmation, click OK to proceed. The Installer window displays information about the progress of the installation, which may take several minutes.

Personal LaserWriter LS: About the Paper Feeder Accessory

I'm confused about the optional paper and envelope feeder for the Apple Personal LaserWriter LS.

Apple's price list states that the Personal LaserWriter LS requires a Personal LaserWriter LS Paper Feeder to accept the optional Letter, Legal, and Envelope cassettes.

I've read all the available Personal LaserWriter LS literature and can find no other mention of the Paper Feeder. Do I really need to get the Paper Feeder, and where do I get more information about it?

This article has been archived and is no longer updated by Apple.
The Personal LaserWriter LS has two standard ways to feed-in paper:

* Manual feeding using the multi-purpose tray, or
* stacking 50 pieces of paper or less in the multi-purpose tray.

There is an optional, dealer-installable, Personal LaserWriter LS Paper Feeder that works with the Personal LaserWriter Letter Cassette, Personal LaserWriter Legal Cassette, or Personal LaserWriter Envelope Cassette.

You don't need the Personal LaserWriter LS Paper Feeder to use the printer. It is only necessary if you want to have a 250-sheet capacity Personal LaserWriter Letter Cassette or Personal LaserWriter Legal Cassette, or the handy Personal LaserWriter Envelope Cassette.

The Personal LaserWriter LS Paper Feeder documentation is in the Personal LaserWriter LS Owner's Guide on pages 79-86.

The Apple part number for the Personal LaserWriter LS Paper Feeder is M8028G/A.

The Apple Personal LaserWriter LS product sheet (M1076LL/A) mentions the Personal LaserWriter LS Paper Feeder under the "Related Products" section.

Unix Deployment Time Zone Error

This article discusses a common problem encountered while running version 4.2 of Portable Distributed Objects or version 3.5.1 of WebObjects on Solaris or HP-UX platforms.

This article has been archived and is no longer updated by Apple.

Q: Why do I get the error message

```
*** Could not find data for default time zone, using GMT
```

when running my OPENSTEP or WebObjects program on Solaris or HP-UX? The same program runs fine on other platforms.

A: This error is caused when the /etc/zoneinfo/localtime symbolic link is missing or pointing to a non-existing directory. This problem can happen after running the PDO 4.2 Install Script.
To fix the problem, you should su to root and do the following:

1) Remove the symbolic link if it exists.
2) Recreate the symbolic link. The commands will look something like:

```
cd /etc/zoneinfo
ln -s US/Pacific localtime
```

You can get a list of all the available timezones under the /etc/zoneinfo directory.

DEC 21X4X OPENSTEP Driver Overview

This article discusses a device driver for the OPENSTEP Mach operating system, versions 4.0 through 4.2.
This article has been archived and is no longer updated by Apple.
Driver: DEC21X4XNetwork
Last Update: February 5, 1998

Availability Information

An updated release version of this driver, version 4.01, is avaiable on Apple's FTP servers at:
ftp://ftp.info.apple.com/Apple_Support_Area/Apple_Software_Updates/MultiCountry/Enterprise/openstep/drivers/released/DEC21X4X.pkg.compressed

Driver Name / Installer .pkg: DEC21X4XNetwork
Driver Type: Networking
Driver Scope: Generic-Chipset
Supported Components: DEC DECchip21040, DEC DECchip21041, DEC DECchip21140, DEC DECchip21142, DEC DECchip21143
PC Bus / Interface Supported by Driver*: PCI

General Overview notes: This driver supports PCI-bus network adapters or on-board network adapters based on DECchip 21X4X LAN Controller. This includes the 21040, 21041, 21140, 21142, and 21143 LAN Controllers. Both 10Mb/s and 100Mb/s connection speeds are supported.

Supported Products / Add-on Adapters:
Adaptec-Cogent ANA-6911A/TX
Cogent EM110-TX Fast Ethernet 10/100 Adapter
Cogent EM960 PCI
DEC DE500 (21143 based) PCI 10/100
DEC DE500 Fast EtherWORKS PCI 10/100
DANPEX PCI Ethernet (EN-9400P3)
SMC 9332 Fast Ethernet 10/100 Adapter
SMC PCI EtherPower (SMC 8432)

Supported Products / Systems (ie integrated into PC System):
DEC Celebris GL On-Board LAN Adapter (21142/21143, 10 Mb/s module)
DEC Celebris GL On-Board LAN Adapter (21142/21143, 10/100 Mb/s module)

Special Features of Driver / Driver Notes:
This device driver provides information in the Configure application's help panel. Choose Info>Help from the Configure menu and scroll down to find this device driver's help topic.

Networking Driver Details

Network Type*: 100 Base FX, 100 Base T4, 100 Base TX, EtherNet, Full Duplex
Speed*: 10 Mb/s, 100 Mb/s
Access Mode*: Bus Master DMA
Buffer Size*: NA
Supported Connectors*: AUI, BNC, UTP

Driver Version Notes

4.00 - Initial release
4.01 - Fixed a SROM parsing bug which prevented the driver from working with the ANA-6911A/TX cards.

* - Indicates information that is inclusive of the entire capability of this driver. Not all devices supported by this driver may include all features listed.

EOF 2.2 EODeleteRuleNoAction patch

This README document describes how to install an EOModeler bundle used with the Enterprise Objects Framework version 2.2 and WebObjects Release 3.5.1 in order to properly set the EODeleteRuleNoAction option in the EOModeler relationship inspector.

The EODeleteRuleNoAction is a new option added to EOModeler starting with EOF Version 2.2.

This EOModeler bundle is the fix for Apple bug ref. no. 2202107.

The WebObjects Current Patch List, **TIL article 70037**, contains information on all available patches and workarounds for all versions of WebObjects, including EOF patches. The OPENSTEP Current Patch List, **TIL article 70033**, contains information on all available patches and workarounds for all versions of OPENSTEP, including EOF patches. Please read these documents if you're not sure which patches you need on your system.
This article has been archived and is no longer updated by Apple.

Bug Description

The bug occurs when you use the Advanced EORelationship inspector to set a relationship's DeleteRule to "No Action" in an eomodel file. When you attempt to open this model at a later point in time, the delete rule will be mistakenly set to "Nullify", and you will see the following message in the console or application event log:

```
Invalid delete rule string:'EODeleteRunNoAction' on entity with name: 'toMovie'
```

Bug Workarounds

1) From within your application you can use the public API on EORelationship to set the EODeleteRule to be the desired value. This can be done with the following code sample:

```
// need to import EOClassDescription.h from EOControl where the
// enum is defined.

-(void)deleteRuleFix
{
// find out the relationship which needs to be fixed
   relToFix = [[[EOModelGroup defaultGroup] entityNamed:@"entityName"] relationshipNamed:@"relName"];
// set to the proper delete rule
   [relToFix setDeleteRule:EODeleteRuleNoAction];
}
```

2) Or you can load the DeleteRuleFix.bundle into EOModeler and any model written out will be correct. Download the NT version of the patch from:

ftp://ftp.info.apple.com/Apple_Support_Area/Apple_Software_Updates/MultiCountry/Enterprise/EOF/patches/2.2/EODeleteRulePatchNT.tar.gz

Or the 3-way fat Mach patch (intel, m68k, and sparc) from:

ftp://ftp.info.apple.com/Apple_Support_Area/Apple_Software_Updates/MultiCountry/Enterprise/EOF/patches/2.2/DeleteRule.bundle.compressed

Installation of the DeleteRuleFix.bundle

First, you need to install the bundle. Then, we recommend that you drop the bundle into the Resources directory of the EOModeler.app. You also need to set the user defaults to get EOModeler to load the bundle during startup.

On NT (using the Bourne shell shipped with WebObjects):
<<Assuming that your $NEXT_ROOT is defined as C:/Next, that you have renamed the binary file to DeleteRuleFix.tar.gz, and that you have copied the NT binary patch into your C:/temp directory>>

```
% cd $NEXT_ROOT/NextDeveloper/Apps/EOModeler.app/Resources
% cp c:/temp/DeleteRuleFix.tar.gz .
% gzip -d DeleteRuleFix.tar.gz
% gnutar xf DeleteRuleFix.tar
% rm DeleteRuleFix.tar
% defaults write EOModeler BundlesToLoad "(c:/Next/NextDeveloper/Apps/EOModeler.app/Resources/DeleteRuleFix.bundle)"
```

On Mach, first decompress the file DeleteRule.bundle.compressed by using the Workspace File menu "Decompress". Then, you'll need to su to root in order to install the bundle:
<<Assuming that Workspace is placing the decompressed file into the default location: /tmp/O_DeleteRule_bundle/DeleteRuleFix.bundle >>

```
% su
Password:
```

```
# cd /NextDeveloper/Apps/EOModeler.app/Resources
# cp -r /tmp/O_DeleteRule_bundle/DeleteRuleFix.bundle .
# exit
% defaults write EOModeler BundlesToLoad "(/NextDeveloper/Apps/EOModeler.app/Resources/DeleteRuleFix.bundle)"
```

Testing for a proper installation of the patch

1. During launch, EOModeler will log the bundles that it loads. So look for the following message in the console of the Application event log, which means that the installation was correct:

```
Dec 11 16:01:05 EOModeler[17673] Loading bundle with path /NextDeveloper/Apps/EOModeler.app/Resources/DeleteRuleFix.bundle:
NSBundle </NextDeveloper/Apps/EOModeler.app/Resources/DeleteRuleFix.bundle> (not yet loaded)
```

2. Modify an EORelationship to have a delete rule of "No Action", save the mode, and then revert. If the Relationship is still set to "No Action", the bundle is loaded.

Note that if you have your own tool that you use to create or modify EOModels, you will need to load this bundle into that tool also in order to preserve the EODeleteRuleNoAction setting.

EOF 2.2 LeakTester Example

There has been substantial interest in the difficult task of finding and fixing leaks in Enterprise Objects Framework, OpenStep, and WebObjects applications. As the EOF team was preparing for the final release of WebObjects 3.5, they wrote a small test app to help them find leaks in the framework. This example will help you learn how to write an application that should be able to run indefinitely with running out of memory. Also, if you think you have encountered a serious leak in the framework, you can use this app as a minimal test case for illuminating the problem.

This article has been archived and is no longer updated by Apple.

The LeakTester app takes a few input arguments:

-batchsize m [number, default 1]
-runs n [number, default 1]
-trials t [number, default 1]
-hang yn [YES/NO, default NO]

For each trial, at runtime the app will, using the Movies EOmodel:

- Empty the tables
- Insert movies (insert m * n movies)
- Add directors and actors (m*n objects fetched, m*n to-one faults fired, m*n to-many faults fired, m*n+m^2*n objects inserted)
- Modify objects (m*n objects fetched, m*n to-one faults fired, m*n to-many faults fired, m*n+m^2*n objects faulted in, m*n objects deleted, m*n objects inserted, m*n+m^2*n objects mutated)

The -hang option makes the app pause before quitting. This allows you to use pview or ps after the app finishes, rather than monitoring the app during its entire run.

The LeakTester source code can be downloaded from:

ftp://ftp.info.apple.com/Apple_Support_Area/Apple_Software_Updates/MultiCountry/Enterprise/EOF/examples/LeakTester.m

You'll need to drop the Movies EOmodel into the app before compiling.

The following results were obtained on Windows NT, using pview.exe to examine the image at the end of the run. This app has only been tested using EOF 2.2, the EOF version that ships with WebObjects 3.5. You might notice that the results aren't quite as deterministic as one might hope, but this is the raw untouched data we got.

Intel and non-Intel processor compatibility

This article discusses processor compatability for NeXTSTEP and OPENSTEP systems.
This article has been archived and is no longer updated by Apple.
The Intel versions of NeXTSTEP and OPENSTEP have been tested on Intel 486, Pentium, and Pentium Pro processors. These are the only processors Apple supports for use with NeXTSTEP and OPENSTEP.

Some companies offer other x86 binary-compatible processors, such as the AMD K6, the Cyrix 5x86 and 6x86, and the Intel Pentium II. How well NeXTSTEP and OPENSTEP will run on these systems depends on how well their manufacturers implement x86 binary support. Our development tools do not optimize code for specific processors, so code developed on any of these systems will run on any other x86 or compatible processor.

Apple Enterprise Software has had reports of system instability while running NeXTSTEP and OPENSTEP on Cyrix 6x86-based systems. For this reason, we cannot recommend running NeXTSTEP or OPENSTEP on 6x86-based systems.

Multiple Inheritance in Objective C

This document describes a technique for simulating C++ style mutual inheritance in Objective C.
This article has been archived and is no longer updated by Apple.

Multiple inheritance is a technique, used in C++ and some other object-oriented languages, whereby an object can inherit data and behavior from multiple superclasses. For the sake of simplicity, Objective C does not include multiple inheritance directly. Most of the time, using protocols or categories instead is a better solution. However, thanks to dynamic typing, you can also provide much of the function of multiple inheritance using OpenStep's implementation of NSObject. Here's how:

+ Create the classes from which you want your subclass to inherit. Be sure that your classes preserve encapsulation: you will not have direct access to your superclass' public instance variables.

+ Create a new subclass of NSObject and give it one instance variable: an array of objects of type id.

+ Create an init method that initializes one instance of each object from which you want your new object to 'inherit' and adds it to the array.

+ Override the forwardInvocation: method in your subclass. Your new method needs to do the following:
- Step through the array, testing each element with respondsToSelector: and the selector specified by the invocation. - If any array element responds to the selector, invoke the message on that element.
- If no element responds to the selector, call [self doesNotRecognizeSelector].

+ If you need to, override your subclass' respondsToSelector: method. This will not be necessary in most cases. The default implementation of respondsToSelector: does not recognize forwarding; that is, your new object will return NO to [myMIObject respondsToSelector:foo] even if it is able to forward foo messages to one of the elements of its array. Your new respondsToSelector method should:
- Step through the array, testing each element with respondsToSelector: and the selector specified.
- If any array element responds to the selector, return YES.
- If no array element responds to the selector, manually test the selector against each of your class' class and instance methods, if any.
- If your class does not respond to the selector, return [super respondsToSelector] to check the methods inherited from NSObject.

Since forwardInvocation: is only called if your new object can't respond to a message, you can override classes from either 'superclass' just as you would if they were true superclasses.

This particular implementation allows you to change the 'inheritance' of your object at runtime by changing the array; you could of course design a class along similar lines using statically typed instance variables instead of an array. This would allow you to design superclass objects that could communicate directly with each other through delegation or notification.

For more information on the techniques used here, see the Foundation framework documentation on the **NSObject** class, the **NSObject protocol** (for respondsToSelector:), and the **NSInvocation** class.

Rhadsody Developer Release Filesystem

The Rhapsody Developer Release (RDR) has a fundamental incompatability with OPENSTEP/Mach (and NeXTStep) that you should be aware of when planning how to install and evaluate this software. Specifically, RDR/Intel uses a different file system format than either RDR/PPC or OPENSTEP/NeXTStep. You will not be able to set up systems to dual-boot RDR/Intel and previous Mach/Intel operating systems. You will also not be able to exchange external hard disks and/or removable media between RDR/Intel and other versions of Mach. Rhapsody/PPC will be able to read (mount read-only) media created on previous versions of Mach. Read/write access to older media is not supported.

This article has been archived and is no longer updated by Apple.

The specific technical issues are as follows:

OpenStep/Mach (all versions) used the original m68k UFS file format, for all architectures. Where necessary (Intel, etc) it was programmed to do byte-swapping on the file system structures as it read them off the disk.

The DR1 release of Rhapsody (for both PPC and Intel) does not have this byte-swapping code in it, so the two systems are currently using incompatable file system formats. It happens that the PPC version has the same byte sequence that the original m68k system used, so that Rhapsody/PPC can read OpenStep/Mach disks created on any architecture. Rhapsody/Intel can't read anyone else's disks.

In addition, the RDR native file system is based on the BSD4.4 file system. Previous Mach versions used the BSD4.3 file system format. The new file system supports huge (64 bit offset) files, and has some other changes. RDR only supports read access to the older file system.

Macintosh: Remote Access to UNIX Servers

Article Change History

08/31/92 - REVIEWED
o For technical accuracy.

I want to access a UNIX server with my Macintosh using dial-up phone lines and modems.

What software do I need to do terminal emulation and file transfer?

This article has been archived and is no longer updated by Apple.

Many Macintosh communication programs, such as MacTerminal, MicroPhone, Smartcom II, Kermit, MacBLAST, VersaTerm, and so on, have VT100, VT52, VT102 terminal emulation. These programs also have file transfer protocols, such as X/Y/Zmodem, Kermit, MacBinary, and so on.

Most UNIX machines support these types of terminal emulation. As long as your UNIX machine has the same file transfer protocol (such as Kermit, or X/Y/Z Modem) as your Macintosh software, there should be no problem doing file transfers.

NeXTSTEP 3.3 Driver: Yamaha OPL Audio

This document discusses a device driver for the NeXTSTEP operating system, version 3.3. This driver will not work with any version of OPENSTEP.
This article has been archived and is no longer updated by Apple.

Availability Information

An updated BETA version of this driver, version 3.30, is avaiable on Apple's FTP servers at:
ftp://ftp.info.apple.com/Apple_Support_Area/Apple_Software_Updates/MultiCountry/Enterprise/nextstep/drivers/beta/YamahaOPLAudio.pkg.compressed

Driver Name / Installer .pkg: YamahaOPLAudio
Driver Type: Sound
Driver Scope: Product Family
Supported Components: Yamaha OPL3-SA (YMF701B), Yamaha OPL3-SA3 (YMF715)
PC Bus / Interface Supported by Driver:** Integrated, ISA

General Overview notes: This driver supports Yamaha OPL3-SA and OPL3-SA3 based audio adapters.

Supported Products / Add-on Adapters:
Yamaha OPL3-SA3 (YMF715) based PNP audio adapters
Yamaha OPL3-SA (YMF701B) based on-board audio adapters

Supported Products / Systems (ie integrated into PC System):

Special Features of Driver / Driver Notes:

Sound Driver Details

Supported Connectors: 1/8" Microphone In, 1/8" Stereo Line-In, 1/8" Stereo Line-Out, 1/8" Stereo Speaker
Access Mode: PIO
Adapter Memory:
Attributes: 16-bit Linear, 8-bit Linear, 8-bit Mu Law

Known Problems

Driver Version Notes

3.30 - First driver for Nextstep 3.3.

EOF 2.1 DB2 Adaptor Creation

This script modifies the ODBC adaptor example source code so that it can access DB2 databases. Building the modified adaptor requires IBM's DB2 CLI SDK; running it requires the DB2 CLI client libraries. Contact IBM directly for more information on these products, or visit their web page at:

http://www.software.ibm.com/data/db2

This script was written using EOF 2.1 installed on Windows NT and Solaris, and tested with DB2 version 2.1.2 and with a beta copy of version 5. It is provided as-is, and is not supported on any platform.
This article has been archived and is no longer updated by Apple.

Why It Works

Because the ODBC and DB2 API's are both based on the CLI specification, they are roughly source code compatible. This script allows you to recompile the ODBC adaptor against the DB2 CLI headers; a simple name change allows it to coexist with the ODBC adaptor. The new adaptor classes will be identical to the classes discussed in the ODBC adaptor class documentation.

Creating the DB2 Adaptor

+ Download the script from:

ftp://ftp.info.apple.com/Apple_Support_Area/Apple_Software_Updates/MultiCountry/Enterprise/EOF/examples/odbc2db2

+ The ODBC adaptor source code example is not installed by the Solaris default installation. If you want to compile under Solaris, you will need to copy these files from an NT machine.

+ Modify the script if necessary. The ODBCDIR variable controls where the script will look for the ODBC example (the default is /NextDeveloper/Examples/EnterpriseObjects/ODBCAdaptor). The DB2DIR variable controls where the script will write the new DB2 example; the default is /NextDeveloper/Examples/EnterpriseObjects/DB2Adaptor).

+ Run the script. On Solaris, from a terminal shell, cd to the appropriate directory and type "./odbc2db2". On NT, use the command "sh odbc2db2".

+ Using ProjectBuilder or a text editor, open the Makefile.preamble-winnt or Makefile.preamble-solaris file appropriate to your build platform. Set the value of the DB2_DIR variable to the location of your DB2 SDK (the default values are C:/SQLLIB for NT and /opt/IBMdb2/V2.1 for Solaris).

+ If you are installing under Windows NT, set the install directory using ProjectBuilder's project inspector panel. On Unix, change the INSTALLDIR variable in the project's Makefile.

+ Build and install the framework. On NT, use ProjectBuilder's project panel; on Unix, cd to the project directory and type "make". You will see compilet warnings during the compilation process; ignore them.

Using the DB2 Adaptor

DB2 databases have a two level naming scheme consisting of a schema and a table. When creating a new model, the default entity names will be a concatenation of schema name and table name. The default schema name is the user's name. To modify that, specify the schema name in the connection string; i.e, use a connection string of the form DSN=dbname,UID=username,PWD=password,SCHEMALIST=schemaname. Optional keywords may also be specified in the DB2CLI.INI file.

More information

This script is provided as-is and is not supported by Apple Enterprise Software. For more information on using DB2, visit IBM's DB2 web page at:

http://www.software.ibm.com/data/db2/library/

For the most current information on what SDKs Apple offers, point your web browser to:

http://developer.apple.com/sdk/

C++ Versus Objective C

"I already know C++. Why do I have to learn Objective C?"

Objective C and C++ are different in their design and intent. C++ extends and modifies C significantly to create a new object-oriented language. The complexity of these changes sometimes leads to confusing interactions between features. Learning C++ can be a lengthy process, and without a stable standard, differences between C++ compilers can add to the confusion.

Objective C is a set of simple extensions that provide ANSI C (or C++) with a simple but powerful standard object model. Most C programmers will be able to learn enough Objective C for most applications in a few days.

Because of this difference in design philosophy, each language has its own benefits and limitations. OPENSTEP's development tools give you the widest range of possibilities by allowing C programmers to write object-oriented code quickly with Objective C, while allowing C++ programmers to mix Objective C and C++ in their projects. Because of its simplicity, Objective C does lack some features that C++ provides; however, most of C++'s functionality can be accessed in other ways in Objective C. Apple also allows you to use all of the features of C++ by including native C++ objects in your OPENSTEP or WebObjects programming projects.

This article has been archived and is no longer updated by Apple.

Benefits of C++

Some of the unique features of C++ are:

+ Multiple inheritance

Objective C, like Java, does not support multiple inheritance. Instead, it allows the user to define a **protocol**. Declaring an Objective C class to conform to a protocol is similar to declaring a Java class to implement an interface; it defines a standard set of methods (member functions) that the class must respond to. Another object can check at runtime to see if a particular class conforms to a particular protocol. Thus, Boat would be a subclass of Vehicle and Duck would be a subclass of bird, and both would conform to the FloatingThings protocol. Unlike with multiple inheritance, only method declarations (member function declarations) are included, not definitions or instance variables (data members). Alternatively, the dynamic nature of Objective C allows you to simulate multiple inheritance: see **article 72567** for details.

+ A **friend**-ly language

C++ gives finer access control over all of an object's elements than Objective C, with private, public, and protected keywords and the concept of **friend** functions. Objective C does allow instance variables (data members) to be set as public, private, or protected, but does not have an equivalent construct for methods (member functions).

```
+ iostream.h
```

C++ provides a new implementation of the ANSI input/output library for stream-based i/o. Objective C does not have an analogous library, but some implementations of Objective C++ do allow you to call the C++ iostream library from your Objective C++ projects.

Benefits of Objective C

+ Dynamic typing and the id type

Any variable in an Objective C object may be declared as type id, meaning a pointer to an object of an undetermined type. The type can be determined at run time, and the appropriate messages sent. Using Objective C's SEL type, you can determine at runtime which message is sent to the object, and therefore what method (member function) is accessed. To avoid runtime problems, the programmer can also test at runtime (with the respondsToSelector: method) to see which messages an object recognizes. Class methods (static member functions) are also available; unlike C++ classes, Objective C classes are true objects and exist at runtime.

+ Categories and dynamic loading

The dynamic nature of Objective C allows existing classes to be extended at runtime. Objective C allows you to define categories, related sets of extensions to objects you've already created. For example, in converting a text-based app into a graphics app, the code your objects needed to draw themselves could be compiled as a category and loaded at run-time

only when needed. This saves memory and allows you to leave your original objects unmodified.

+ Simple and standard

C++ is a complex and evolving language, leading to differences between compilers and implementations; as a result, C++ users need to be more careful about using features like boolean types that may not be supported on all compilers. Objective C 's simplicity makes these problems less likely; it has also helped it maintain a stable standard. (And yes, Objective C does have a BOOL data type.)

+ Shortcuts

C++ doesn't have a monopoly on convenient features, either. Objective C's additions include C++-style // comments and the #import directive, which acts like the #include directive but ensures that each referenced file is included only once per project.

An Objective C Primer

A C++ programmer who starts working in Objective C is likely to notice the differences in syntax before the more subtle differences in implementation. For example, a call to a C++ Employee class instance's promoteToManager member function might look like this:

```
anEmployee.promoteToManager();
```

In Objective C, this same call would look like this:

```
[anEmployee promoteToManager];
```

A similar call with two arguments in C++...

```
anEmployee.promote(newPosition, newSalary);
```

...would look like this in Objective C:

```
[anEmployee promoteToPosition:newPosition atSalary:newSalary];
```

Here, the member function being called (in Objective C terminology, the instance method being messaged) is called promoteToPosition:atSalary:

Objective C's syntax and naming conventions are discussed in more detail in the book *Object-Oriented Programming and the Objective C Language*. This book also contains information on combining Objective C and C++ code in OPENSTEP projects and goes into more detail on the principles behind Objective C's object model. It is available as part of OpenStep's online documentation, or printed copies can be purchased from Apple Enterprise Software. More information, including a link to the Objective C Usenet FAQ, is available from the GNU Objective-C Project at http://world.std.com/~gsk/gnu-objc.html .

Password Protecting OPENSTEP for Mach in Single User Mode

The ability to boot a UNIX system in single-user mode is a security concern, since single-user mode provides a root shell without requiring a password. This example allows you to force the user of an OPENSTEP for Mach system to supply a password before /bin/sh starts in single user mode. It does this by running a password checking program in the shell's startup file for root, /.profile. This document assumes that you are using OPENSTEP for Mach version 4.2.

This article has been archived and is no longer updated by Apple.

Disclaimer

This procedure has been tested for security holes, and appears to resist concerted efforts to defeat it. However, Apple disclaims any warranty of any kind, expressed or implied, as to its fitness for any particular use. This procedure has not been tested under any version of MacOS X Server.

This script may not work if the password you use is more than eight characters long. Remember to test the script immediately after installing it to be sure your password is being fetched correctly.

Required Files

The files needed for this example are available in compressed form on Apple's FTP site, at:

ftp://ftp.info.apple.com/Apple_Support_Area/Apple_Software_Updates/MultiCountry/Enterprise/openstep/examples/PW_Protected_SU.compressed

This archive includes:

- The pwcheck.c source code
- The makefile
- A sample /.profile file that runs the compiled example
- An RTF copy of this instruction file

Using Password Protection

To password protect single-user mode on your system, simply log in to a Unix shell as root, cd to the uncompressed directory containing the Makefile and source code and type "make." The pwcheck Makefile will automatically install the pw_check program and /.profile, place your local NetInfo domain's root password in your local /etc/password file, and protect your /etc/rc.boot file so that the startup sequence cannot be interrupted from the keyboard. Backup copies of your original files are created as /etc/passwd.orig, /etc/rc.boot.orig, and /.profile.orig.

The program prompts the user three times to enter a password. The default .profile included with this package will prompt for the root password, but you may specify another user's password in the command line. If the correct password is not entered in three attempts, the program halts the processor, shutting down the computer system.

AppleWorks: Using With Wide Carriage ImageWriter

This article discusses how to use AppleWorks with the Wide Carriage ImageWriter.
This article has been archived and is no longer updated by Apple.
AppleWorks can print over the entire width of the Wide Carriage ImageWriter's platen. How you do it depends on whether you're using AppleWorks' word processor, datbase, or spreadsheet module:

- In the word processor or spreadsheet, press Open-Apple-O, set PW (platen width) to 13.2, and press Escape.

- In the database, press Open-Apple-O when in a Report Format and set PW (Platen Width) to 13.2.

To print the maximum number of characters per line, change the Characters per Inch setting to 17. This allows up to 224 characters per line.

Apple IIGS: Error 0C Indicates Sound Chip Problem

My Apple IIGS (rev. 03 ROM) gives a self test error code of 0C000004, though everything seems to be working fine. What does this code mean?
This article has been archived and is no longer updated by Apple.
Apple IIGS Tech Note #95 explains the diagnostics test:

```
AA = 0C
DD = 01:  RAM data error
     02:  RAM address error
     03:  Data register failed
     04:  Control register failed
     05:  Oscillator interrupt timeout
```

In your case, the problem is a control register failure, specifically a bad sound chip. Since the sound chip is not socketed, you will have to replace the logic board of the Apple IIGS.

The following Tech Info Library article can help you find the Tech Note mentioned here:

Using the GDB Debugger

Gdb is the debugging tool used to debug WebObjects and OPENSTEP applications, and an integral part of the Apple Enterprise development environment. This document is designed to help you use gdb to quickly debug and test your applications.

This article has been archived and is no longer updated by Apple.

Breakpoints

Setting and Managing Breakpoints

To set a breakpoint, type **break** or **b** and the name of the function or method where you want to halt execution:

(gdb) break main

or

(gdb) b main

If the method you specify is implemented by several classes, gdb presents a list for you to choose from. At the prompt, type the number of the function or method where you want the breakpoint to be set.

```
(gdb) b init
[0] cancel
[1] all
[2] -[MovieMgr init] at MovieMgr.m:10

Non-debugging symbols:
[3] -[ColoredRanges init]
[4] -[EOAccessGenericFaultHandler init]
[5] -[EOAttribute init]
[6] -[EODelayedObserverQueue init]
[7] -[EOEditingContext init]
[8] -[EOEntity init]
.
.
.
[92] -[WOApplication init]
[93] -[WOComponent init]
[94] -[WOContext init]
[95] -[WODisplayGroup init]
[96] -[WODynamicURLString init]
[97] -[WOElementIDString init]
[98] -[WOEncodingDetector init]
[99] -[WOPageSessionStore init]
> 2
Breakpoint 5 at 0x40100a: file MovieMgr.m, line 10.
(gdb)
```

You can also specify the class along with the method name:

(gdb) break [MovieMgr init]

Remember that in Objective-C, if a method takes arguments, you must include the colons as part of the method name:

(gdb) break [MovieMgr setCurrentBatchNumber:]

If you need to put a breakpoint inside a function or method instead of at the start, you can specify stops by line number or by code address. Gdb interprets a breakpoint on an integer as a break on that line in the current source file. To set a breakpoint in a different file, specify the file name followed by a colon and the line number. To break at a code address, type the address preceded by an asterisk:

```
(gdb) break 10 break at line 10 in the current rile
(gdb) break MyObject.m:l0 break at line 10 in tile MyObject.m
(gdb) break *0x50069b4 break at the specified address
```

To find the line numbers of the next few commands to be executed from the current source file, use the **list** command.

```
(gdb) list
19
20 - (void)fetchMovies
21 {
22 EOFetchSpecification *fetchSpec;
23
24 ec = [[WOApp session] defaultEditingContext];
25 fetchSpec = [EOFetchSpecification fetchSpecificationWithEntityName:@"Movie"
26 qualifier:nil sortOrderings:nil];
27 movies = [ec objectsWithFetchSpecification:fetchSpec];
28 }
(gdb)
```

Once you have set your breakpoints, use the **info break** command to list them by breakpoint number:

```
(gdb) info break
Num Type Disp Enb Address What
3 breakpoint keep y 0x00401053 in -[MovieMgr fetchMovies] at MovieMgr.m:24
breakpoint already hit 1 time
4 breakpoint keep y 0x00401099 in -[MovieMgr fetchMovies] at MovieMgr.m:27
5 breakpoint keep y 0x0040100a in -[MovieMgr init] at MovieMgr.m:10
(gdb)
```

Once you know a break point's number, you can selectively enable or disable it with the **disable** (**dis**) and **enable** (**ena**) commands:

```
(gdb) disable 3

(gdb) ena 3
```

Accessing Variables

The **print** command (**p**) allows you to print information about an address, a variable, or a method.

```
(gdb) p fetchSpec
$1 = (EOFetchSpecification *) 0x40104c
(gdb)
```

Every expression you evaluate using the print command is assigned a value number and stored in your session's value history. This value, in the example above $1, can be used in further expressions:

```
(gdb) p [$1 entityName]
$2 = (void *) 0x403020
(gdb)
```

The values in the value history are not affected by scope. This means that $1 doesn't change to hold the new value of fetchSpec when your program enters a different scope.

The **print-object** (**po**) command takes an Objective C object as its arguments, and calls that object's printForDebugger: method. The default implementation of this method, inherited from the NSObject class, simply prints out the class name and hex address of the object:

```
(gdb) po ec
<EOEditingContext: 0x4463a0>
(gdb)
```

You can override this method in your classes to provide more useful data about a given object at run-time for debugging purposes. Many Foundation and AppKit objects, such as NSString and NSArray, already do this.

The **print** and **po** commands accept any valid Objective-C expression, including nested messages:

```
(gdb) p [[movies objectAtIndex:0] editingContext]
$2 = (void *) 0x4463a0
(gdb) po $2
<EOEditingContext: 0x4463a0>
(gdb)
```

Other Commands

next or **n** takes you to the next line of the current source file.
step or **s** steps into a method.
view or **v** highlights the line you are on in your source code in ProjectBuilder.

At any time, $ refers to the last value in history and $$ to the next-to-last value.

Pressing the enter key at the gdb prompt without typing a command repeats the last command executed.

Customizing GDB

Convenience Variables

Any name that begins with a `$' can be used as the name of a gdb **convenience variable**. These variables are implicitly typed and created at first reference. Use **print** to get the value of a convenience variable and **set** to set or change the value. You can use any valid C or Objective-C expression, including dynamically called methods or functions:

```
(gdb) p $myArray = [NSArray array]
$1 = (void *) 0x42f490
(gdb) po $1
()
(gdb) po $myArray
()
(gdb) p $num = 1230 % 4
$2 = 2
(gdb)
```

All registers have convenience variables associated with them. The **info registers** command dumps the contents of all registers so you can see the names associated with each register. The register convenience variables most often used are $fp, which holds the frame pointer, $sp for the stack pointer, and $pc for the program counter.

User-Defined Commands

As you learn more gdb features, you may want to create shorthand aliases for commands or macros of common command sequences. The **define** command allows you to choose a name to be associated with a command or sequence of commands. These user-defined commands become fully integrated in gdb: You only need type enough of the name to distinguish it from other commands, and the commands are listed in gdb's help system. You can even use the **document** command to enter documentation for your new command; this documentation is provided when you ask for **help** about the command.

```
(gdb) define pools
Type commands for definition of "pools".
End with a line saying just "end".
>p [NSAutoreleasePool showPools]
>end
(gdb) document pools
Type documentation for "pools".
```

End with a line saying just "end".
>Prints descriptions of the autorelease pools
>end
(gdb) help pools
Prints descriptions of the autorelease pools
(gdb)

User-defined commands can not take arguments. However, you can work around this is by using a convenience variable, with its value set prior to executing the command.

Preferences

Gdb's preference settings control editing, history, printing, and other behavior in the gdb environment. To see the full list of preferences and their current settings, use the **info set** command.

(gdb) info set
confirm: Whether to confirm potentially dangerous operations is on.
prompt: Gdb's prompt is '(gdb) ".
editing: Editing of command lines as they are typed is on.
verbose: Verbose printing of informational messages is on.
autoload-breakpoints: Automatic reseizing of breakpoints in dynamic code is on.
. . .

One preference setting commonly changed is **print elements**. When you print an array or string using the print command, gdb prints elements only up to the limit specified by this preference. By default the limit is set to 200; you can disable the limit by setting it to 0.

Initialization Files

A **.gdbinit** file consists of gdb commands as they would be typed at the command prompt. When gdb starts up, it reads the commands from the .gdbinit file in your home directory, then the .gdbinit file from the current project directory, and finally from the system .gdbinit file in /usr/lib. Use your personal .gdbinit file to set your preferences, and the system file to add path inclusions for subprojects and to define project-specific commands.

Advanced Debugging Techniques

Backtraces

Gdb provides a set of commands that allow you to examine the state of your application. Use the **backtrace** command (**bt**) to find out where control has come from, based on a list of stack frames. Use the **frame** command (**f**) to choose which of those stack frames is selected. The **info frame**, **info locals**, and **info args** commands provide you with more information about the chosen frame. Remember that gdb's command line interpreter can evaluate any C or Objective-C expression, so when your application is stopped in gdb, you can examine and set variables of your program, make function calls, send messages to objects, and so on.

Backtrace output looks like this:

(gdb) bt
#0 -[MovieMgr fetchMovies] (self=0x439750, _cmd=0x402127) at MovieMgr.m:28
#1 0x401030 in -[MovieMgr init] (self=0x439750, _cmd=0x310255d3)
at MovieMgr.m:12
#2 0x320434c0 in +[NSObject new] ()
#3 0x31017842 in objc_msgSendv ()
#4 0x320410d5 in -[NSInvocation invoke] ()
#5 0x540b4134 in NMSPerformSelector ()
#6 0x540bf01e in -[WOObjCExpression evaluateInScope:debugger:] ()
#7 0x540bb575 in -[WOBinaryExpression evaluateInScope:debugger:] ()
#8 0x540bc8d5 in -[WOExpressionStatement executeInScope:debugger:] ()
#9 0x540c27b0 in -[WOStatements executeInScope:debugger:] ()
#10 0x540bc6a7 in -[WOCompoundStatement executeInScope:debugger:] ()

```
#11 0x540bd45f in -[WOMethod executeInParentScope:debugger:forSelf:arguments:]
()
#12 0x540be5a5 in -[WOModule evaluateMethodNamed:forSelf:count:arguments:inScope
:debugger:] ()

#14 0x540b72dd in -[_NMSScriptedClassShadow _genericVararg:] ()
#15 0x4201d5ad in -[WOComponent(WOComponentPrivate) _initWithName:] ()
#16 0x4201e7bb in -[WOComponentDefinition(WOComponentGeneration) componentInstan
ce] ()
#17 0x42018a5f in -[WOApplication(WOPageManagement) pageWithName:] ()
#18 0x4201932f in -[WOApplication(WORequestHandlingInternals) _handleRequestInPr
eparedSession] ()
#19 0x42019277 in -[WOApplication(WORequestHandlingInternals) _handleRequestInPr
eparedApplication] ()
#20 0x42019915 in -[WOApplication(WORequestHandling) handleRequest:] ()
#21 0x4202a0c5 in -[WODefaultAdaptor handleConnection:] ()
#22 0x3203946f in _postNotification ()
#23 0x32039d6a in -[NSNotificationCenter postNotificationName:object:userInfo:]
()
#24 0x320604ad in -[NSConcreteFileHandle handleMachMessage:] ()
#25 0x3206f0c6 in -[NSRunLoop acceptInputForMode:beforeDate:] ()
#26 0x3206f268 in -[NSRunLoop runMode:beforeDate:] ()
#27 0x42018d75 in -[WOApplication(WORunning) run] ()
#28 0x4012d6 in main (argc=4, argv=0x436430) at main.m:183
#29 0x40144c in mainCRTStartup ()
(gdb)
```

You can then inspect the frames.

```
(gdb) f 12
#12 0x540be5a5 in -[WOModule evaluateMethodNamed:forSelf:count:arguments:inScope
:debugger:] ()
(gdb)
```

If you have the symbols, you can use **info args** to print the function's arguments and **info locals** to print the local variables:

```
(gdb) info args
self = (MovieMgr *) 0x439750
_cmd = (struct objc_selector *) 0x402127
(gdb) info locals
self = (MovieMgr *) 0x439750
fetchSpec = (EOFetchSpecification *) 0x448a80
(gdb)
```

If you do not have the symbols, you can still get to some of the argument information by using the frame pointer and offsets. (These offsets vary based on system architecture.)

```
p *(id *)($fp + 8) - prints the receiver of the message (often the same as self)
p *(SEL *)($fp + 12) - prints the selector (the method that was called)
p *(id *)($fp + 16) - prints argument 1
p *(id *)($fp + 20) - prints argument 2
p *(id *)($fp + 24) - prints argument 3
```

```
(gdb) f 12
#12 0x540be5a5 in -[WOModule evaluateMethodNamed:forSelf:count:arguments:inScope
:debugger:] ()
(gdb) p *(id *)($fp + 8)
$4 = (WOModule *) 0x43ab70
(gdb) p *(id *)($fp + 16)
$5 = (NSInlineCString *) 0x428ff0
(gdb) po $5
```

```
init
(gdb) p *(id *)($fp + 20)
$6 = (WOScriptedClass(/WebObjects/Projects/batch.woa/Main.wo/Main) *) 0x432ea0
(gdb)
```

For convenience, you may want to create user-defined commands for these offsets in your .gdbinit file.

Breakpoint Commands

You may want to execute the same commands each time you hit a given breakpoint. Gdb **breakpoint commands** nicely handle this task. Breakpoint commands enable you to specify a set of commands that gdb executes each time the breakpoint is reached. Any C or Objective-C expressions are allowed, as are other gdb commands such as turning breakpoints on and off or changing auto-display of expressions. You can also use the **silent** command, which causes gdb to skip the usual printing when arriving at a breakpoint, and the **continue** command, which continues execution of your application. The **commands** keyword is used to specify commands to execute; type help commands for syntax information.

For example, if you have introduced some code that causes your application to crash, you can use breakpoint commands to get past the errant code and reach another breakpoint while debugging. Just set a breakpoint right before the misbehaving code, and use the **jump** command to skip over it:

```
- someMethod
{
. .
[anObject free];
. . .
[anobject doOneMoreThing]; // Line #192: Oops, I didn't mean to do this!

. . . .
return self;
}
```

```
(gdb) break 192 Breaks on the line that sends message to freed object
(gdb) commands Starts the set of breakpoint commands
Type commands for when breakpoint 1 is hit, one per line.
End with a line saying just "end".
silent Turns off the somewhat noisy breakpoint announcement
jump 193 Jumps to the next line
continue Continues executing the program
end Ends the set of commands
```

Gdb will now skip over the line that sends a message to the freed object, allowing you to debug other things. At times, it may be more appropriate to use the **return** command to force a return from the current method or function.

You can also test a code fix directly in the debugger, without having to recompile and link your project. For example, if you've forgotten to allocate space for a string, you can insert a malloc call in the debugger:

```
- setStringValue:(const char *)newString
{
char *str;

strcpy(str, newstring); // Line #166: Bad news, forgot to allocate str
return self;
}
```

```
(gdb) break 166 ----> break on strcpy line
(gdb) commands
Type commands for when breakpoint 4 is hit, one per line.
End with a line saying just "end".
silent
print str = (char *) malloc(str,strlen(newString) + 1)
continue
```

end

These breakpoint commands stop before the strcpy, allocate the string, and continues execution. Don't forget to propagate the changes back to your original source code to permanently fix the problem!

Viewing SQL Debugging Output

Use this command to view the SQL that EOF generates as a result of your fetches:

(gdb) defaults write NSGlobalDomain EOAdaptorDebugEnabled YES

This command turns SQL logging off:

(gdb) defaults write NSGlobalDomain EOAdaptorDebugEnabled NO

Debugging Optimized Code

Debugging optimized code sometimes gives surprising results. Control flow may change due to loop invariant statements being moved out of a loop body or common subexpressions being eliminated. The debugger may be unable to set or print the value of a given variable because it doesn't have information necessary to find it. Variables may be moved into registers and two or more variables may share the same register when their live ranges don't overlap. Stack variables that never have their address taken and are used only across a very few instructions can "disappear" without a trace. If you ask gdb to print such a variable, even though the source clearly shows it is in scope, gdb will reply:

(gdb) print num
No symbol "num" in current context.

In this case, the **info locals** and **info args** commands will also report there is no record of the variable. To ensure that your variables are available to the debugger even after optimization, declare the variable **volatile**.

For More Information

Please see gdb's man page and on-line documentation for more information on the topics covered by this document.

ImageWriter I: Compatible with Newer Macintosh Models (2/96)

I am having difficulty using a Macintosh Classic with a wide carriage

ImageWriter I. Are there any known incompatibilities with old ImageWriter

printers and the new computers or system software?

This article has been archived and is no longer updated by Apple.

There are no known compatibility problems with the ImageWriter I and Macintosh computer with DIN 8 serial ports, if the current ImageWriter driver and the proper cables are used.

The current ImageWriter driver is version 2.7 for System 6 users and version 7.0.1 for System 7.x users. The correct cable configuration is to use the original Macintosh to ImageWriter DB-9 to DB-25 cable, part number 590-0169, with the DB-9 to Mini DIN 8 Macintosh Peripheral Adapter cable, part number 590-0553.

When using these cables and the current ImageWriter driver, the printer

should work just fine.

Article Change History:

05 Feb 1996 - Made minor change.

06 Jul 1995 - Updated part numbers to reflect current models

EOF 2.2 Database Adaptor Patch Overview

This patch is now obsolete. Please see the WebObjects Current Patch List, **TIL article 70037**, for information on the most current patches for WebObjects and Enterprise Objects Framework. This obsolete patch is provided here as a convenience to our customers who have not yet upgraded to the most current patch level.
This article has been archived and is no longer updated by Apple.

About the EOF 2.2 Sybase Adaptor Patch

The Sybase Adaptor patch fixes two bugs:

All parameters required for Sybase stored procedures
Apple reference # 2203081

PROBLEM:
If you did not supply all values when executing a Sybase stored procedure, the execution would fail with an exception like:

```
Feb 19 11:23:53 WOF_3_5_Sybase_Patch[1027] Caught exception:EOGeneralAdaptorException
Sybase: Server:unknown Procedure:NEXT_MOVIE_PRIMARY_KEY Line:0 Procedure NEXT_MOVIE_PRIMARY_KEY expects
parameter @A_MOVIE_ID, which was not supplied.
```

This happens even though A_MOVIE_ID is not required for the stored procedure.

RESOLUTION:
The Sybase adaptor no longer requires optional arguments to stored procedures.

Cannot fetch float-NSDecimalNumbers along with text columns
Apple reference # 2208497

PROBLEM:
If you have an attribute with external type float, and internal type NSDecimalNumber, it will not fetch properly if a text column is also in the fetch. The attribute will be blank.

RESOLUTION:
The Sybase adaptor now correctly fetches these attributes.

Installing the EOF 2.2 Sybase Adaptor Patch

Windows NT
Download the Sybase patch for Windows NT from Apple's FTP servers at ftp.info.apple.com. The patch is located at:

```
/Apple_Support_Area/Apple_Software_Updates/MultiCountry/Enterprise/EOF/

patches/2.2/Sybase_Patch.NT.gtar.gz
```

To install the patch, open up a shell (from the WebObjects start menu) and issue the following commands as root, replacing the patch file name with the full path of the patch file you downloaded:

```
cd $NEXT_ROOT

gunzip -c Sybase_Patch.NT.gtar.gz | gnutar xvf -
```

OPENSTEP/Mach
Download the Sybase patch for Mach from Apple's FTP servers at ftp.info.apple.com. The patch is located at:

```
/Apple_Support_Area/Apple_Software_Updates/MultiCountry/Enterprise/EOF/

patches/2.2/Sybase_Patch.mach.gtar.gz
```

To install the patch, open up a Terminal and issue the following commands as root, replacing the patch file name with the full path of the patch file you downloaded:

```
cd /
```

```
gnutar xvzf Sybase_Patch.mach.gtar.gz
```

Solaris
Download the Sybase patch for Solaris from Apple's FTP servers at ftp.info.apple.com. The patch is located at:

```
/Apple_Support_Area/Apple_Software_Updates/MultiCountry/Enterprise/EOF/

patches/2.2/Sybase_Patch.Solaris.gtar.gz
```

To install the patch, open up a Terminal and issue the following commands as root, replacing the patch file name with the full path of the patch file you downloaded:

```
cd $NEXT_ROOT

zcat Sybase_Patch.Solaris.gtar.gz | gnutar xvf -
```

HP-UX
Download the Sybase patch for HP-UX from Apple's FTP servers at ftp.info.apple.com. The patch is located at:

```
/Apple_Support_Area/Apple_Software_Updates/MultiCountry/Enterprise/EOF/

patches/2.2/Sybase_Patch.HP-UX.gtar.gz
```

To install the patch, open up a Terminal and issue the following commands as root, replacing the patch file name with the full path of the patch file you downloaded:

```
cd $NEXT_ROOT

zcat Sybase_Patch.HP-UX.gtar.gz | gnutar xvf -
```

About the EOF 2.2 ODBC Adaptor Patch

The ODBC Adaptor patch fixes two bugs:

ODBC Adaptor cannot execute stored procedures with output parameters
Apple reference # 2208503

PROBLEM:
The EOF 2.2 (WebObjects 3.5) version of ODBCEOAdaptor.framework introduced a bug which causes an error when using a stored procedure with an output parameter.

RESOLUTION:
The ODBC adaptor now handles output parameters correctly.

ODBC adaptor leaks connections with Microsoft Access
Apple reference # 2209574

PROBLEM:
The EOF 2.2 (WOF 3.5) and earlier versions of ODBCEOAdaptor.framework did not release ODBC connections when using Microsoft Access (or any JET based data source) in order to work around a bug in the Microsoft odbcjt32.dll library; this bug caused a crash when SQLFreeConnect was called. The SQLFreeConnect bug was discovered in version 3.40.2829 of the DLL. Newer versions of the DLL (beyond 3.50) no longer exhibit the crashing problem.

RESOLUTION:
The patched version of this framework now checks the version of the DLL more carefully and allows SQLFreeConnect to be called unless the DLL version is 3.4X. The adaptor no longer leaks the ODBC Connection when running with fixed versions of odbcjt32.dll.

Installing the EOF 2.2 ODBC Adaptor Patch

Windows NT
Download the ODBC adaptor patch for Windows NT from Apple's FTP server at ftp.info.apple.com. The patch is located at:

```
/Apple_Support_Area/Apple_Software_Updates/MultiCountry/Enterprise/EOF/

patches/2.2/ODBC_Patch.NT.gtar.gz
```

To install the patch, open a shell (from the WebObjects start menu) and issue the following commands as root: (replacing the patch file name with the full path of the patch file you downloaded)

```
cd $NEXT_ROOT

gunzip -c ODBC_Patch.NT.gtar.gz | gnutar xvf -
```

AddObjectIfAbsent: and slow EOF performance

This document describes a problem that can cause memory leaks and slow performance for OPENSTEP and WebObjects applications.

This article has been archived and is no longer updated by Apple.

Apple's Enterprise Objects Framework uses a category to add an **addObjectIfAbsent:** method to NSMutableArray:

```
@interface NSMutableArray (EOPointerBasedManipulation)
- (BOOL)addObjectIfAbsent:object;
   // adds an object to the array if and only if it isn't already in the array
   // return YES if object was not in the array or NO if it already was present
@end
```

Because this method is not documented, some Apple developers and writers of third-party frameworks have added their own **addObjectIfAbsent:** method. When EOF's EOObjectStoreCoordinator makes a call to **addObjectIfAbsent:** to register a notification, it does not receive the expected return value, and two additional notifications are generated. This can seriously affect system performance in applications which make a large number of database fetches. There are three possible solutions to the problem:

--Modify your implementation of the method to return the appropriate values, as shown above

--Modify your code to use Apple's implementation of this method

--Change the name of your custom method so Apple's implementation is not superceded.

Using the Windows NT Wait Cursor With OPENSTEP

Applications built with OpenStep 4.2 Enterprise will not automatically call the Windows NT wait cursor during long operations such as launching applications and loading frameworks. If you know your application is about to begin a long operation, however, you can bring up the NT wait cursor manually. This document contains sample code for calling the NT wait cursor.

This article has been archived and is no longer updated by Apple.

The following sample code demonstrates how to call the Windows NT wait cursor on OPENSTEP 4.2 Enterprise.

```
#ifdef WIN32

#import <Windows.h>
// Apple OpenStep Enterprise NSCursor private initializer method
@interface NSCursor (Secret)
- (id) initWithCursorHandle: (HCURSOR) handle;
@end

#endif

@implementation NSCursor (waitCursor)

+ (NSCursor *) waitCursor

{
static NSCursor *waitCursor = nil;

#ifdef WIN32
if (!waitCursor) {
HCURSOR cursor = LoadCursor(NULL, IDC_WAIT);

if (cursor && [NSCursor instancesRespondToSelector: @selector(initWithCursorHandle:)])
waitCursor = [[NSCursor alloc] initWithCursorHandle: cursor];
}
#endif
return waitCursor;
}

@end

// some class implementation wanting to use a wait cursor

- (void) deactivateWaitCursor

{
#ifdef WIN32
NSCursor * const waitCursor = [NSCursor waitCursor];
NSArray * const windows = [NSApp windows];
const int count = [windows count];
int i;

[waitCursor setOnMouseEntered: NO];
for (i = 0; i < count; i++)
[[windows objectAtIndex: i] resetCursorRects];
#endif
return;
}

- (void) activateWaitCursor

{
#ifdef WIN32
```

```
NSCursor * const waitCursor = [NSCursor waitCursor];
NSArray * const windows = [NSApp windows];
const int count = [windows count];
int i;

[waitCursor setOnMouseEntered: YES];
for (i = 0; i < count; i++) {
NSWindow * const window = [windows objectAtIndex: i];
NSView * const contentView = [window contentView];

[window enableCursorRects];
[contentView addCursorRect: [contentView frame] cursor: waitCursor];
}
#endif
return;
}
```

WebObjects Deployment Problems on HP-UX

This article discusses problems commonly encountered while deploying a WebObjects application on HP-UX.
This article has been archived and is no longer updated by Apple.
Q: I'm trying to deploy a WebObjects 3.5.1 or WebObjects 4 application on an HP-UX 10.20 web server. My applications crash out if I try to use Monitor.app to control more than a few application instances.

A: Because of multithreading limitations on HP-UX, only 15 concurrent Distributed Objects (DO) connections are available to any given process; because Monitor.app uses DO to communicate with applications, monitored apps reach the limit more quickly.

You may be able to increase this limit by increasing the MAXFILES and MAXFILES_LIM kernel parameters on your system. However, if you are running your WebObjects applications on a Mach, Windows NT, or Solaris machine, a better solution is to run monitor.app on that system instead of on the web server. Monitor does not need to run on the web server machine or make DO connections to it, although it does need to make DO connections to the application server. Because monitor.app does require access to the web server's WebObjects.conf file, you will need to provide access to the server machine via NFS or Samba, or, if the WebObjects.conf file does not change, you can use an exact local copy.

OPENSTEP 4.2 for Mach Fax Patch

This patch is now obsolete. It was incorporated into OPENSTEP 4.2 Patch 4. Please see the OPENSTEP Current Patch List, **TIL article 70033**, for information on the most current patches for OPENSTEP and Enterprise Objects Framework. This obsolete patch is provided here as a convenience to our customers who have not yet upgraded to the most current patch level.
This article has been archived and is no longer updated by Apple.
This patch is obsolete; please see the OPENSTEP Current Patch List, **TIL article 70033**, for information on the most current patches for OPENSTEP and Enterprise Objects Framework. This patch was incorporated into OPENSTEP 4.2 Patch 4.

Q: Under OPENSTEP 4.2 for Mach, some applications won't let me set a cover page for faxes--and a few won't let me fax at all! How can I fix this?

A: There was a problem with the English language cover page shipped with OPENSTEP 4.2. All you have to do is replace the file:

```
/NextLibrary/Fax/English.lproj/Cover.draw
```

with a corrected version. You will then be able to fax normally from all applications. You can download this corrected version from:

ftp://ftp.info.apple.com/Apple_Support_Area/Apple_Software_Updates/MultiCountry/

Enterprise/openstep/patches/4.2_Fax_Patch/Cover.draw.compressed

NOTE: Some versions of OmniWeb for OPENSTEP Mach add a .Z extension to downloaded files, causing uncompression errors. To correct this problem, find the downloaded file in the file system and remove the .Z extension before uncompressing it.

Linking Windows NT DLL‘s into WebObjects 3.0 applications

This document explains how to link a DLL into a compiled WebObjects 3.0 application on Windows NT. The procedure also applies to OPENSTEP Enterprise 4.1 on Windows NT.

This article has been archived and is no longer updated by Apple.

In most versions of OPENSTEP and WebObjects, linking a .dll into your project is simply a case of dragging and dropping the library's .lib file into the Libraries folder of your Project Builder project, then using the Inspector to add your library's header files to the project's search order.

However, there was a bug in the version of ProjectBuilder that shipped with OPENSTEP 4.1 and WebObjects 3.0. If you are using either of these versions, do not add the library with the ProjectBuilder browser. Instead, add the library name to the makefile directly, in the OTHER_LIBS keyword. Then put a copy of the .lib file in your application directory under the obj-i386-nextpdo-winnt3.5-opt directory. You will also need to add this value to the OTHER_LDFLAGS keyword:

OTHER_LDFLAGS = $(LIBRARY_PATHS)

These problems have been fixed in OPENSTEP 4.2 and WebObjects 3.1.

A/UX: Directories; 32-bit Clean Warning; Number of Procs (9/94)

Here are a few A/UX questions:

1. I've got an NFS server online. How do I export specific directories (/usr/catman, for example) without exporting root or /usr?

2. How do I prevent the "32-bit clean" warning (for Macintosh applications stored and launched under A/UX file system) without resorting to a ResEdit fix?

3. I know how to increase the maximum number of processes using kconfig. Is it possible to increase my maximum number of PTYs to 64?

This article has been archived and is no longer updated by Apple.
1. All the NFS exported entries specified in the /etc/exports file are file system mount points. Currently, there is no way you can only "export" specific directories under a mounted file system.

We suggest you make and export a new file system for these specific directories.

2. SIZE resource is the only place to make this change. Here are two ways you can make a Macintosh application "recognizable" as a 32-bit clean so as not to get a "32-bit clean..." warning message everytime it is launched:

* use ResEdit
or
* use "changesize +32BitCompatible file" command under CommandShell.

Changesize command sounds easier than ResEdit.

3. Yes, it is possible to change the maximum # of PTYs via kconfig. Just specify the NPTY=64 within kconfig.

WebObjects 3.5.1 Java Patch Overview

This patch is now obsolete. Please see theWebObjects Current Patch List, **TIL article 70037**, for information on the most current patches for WebObjects and Enterprise Objects Framework. This obsolete patch is provided here as a convenience to our customers who have not yet upgraded to the most current patch level.
This article has been archived and is no longer updated by Apple.

About This Patch

This patch corrects several Java-related bugs in WebObjects 3.5.1 for Windows NT and Solaris. It should be installed on all WebObjects 3.5.1 development and deployment systems running on Windows NT or Solaris. This patch also incorporates the changes to the Sybase and ODBC EOF adaptors included in a previously released patch. Once this patch is installed, be sure to read **TIL article # 72624** to learn about a problem that can occur when subclassing customObject and how to avoid it.

Installing WebObjects 3.5.1 Java Patch 2 on Windows NT 4.0

1. Download the Windows NT version of the patch from Apple's FTP site at ftp.info.apple.com. The file is located at:

```
/Apple_Support_Area/Apple_Software_Updates/MultiCountry/Enterprise/webobjects/patches/

3.5.1/3.5.1_Java_Patch_NT.tar.gz
```

2. Log in as a user with Administrator privileges.

3. Open a Bourne shell. The Bourne shell should be available from your Start menu, under the WebObjects program group, or under your Apple root directory at Demos\\sh.exe.

4. Type the following at the shell prompt (make sure that there are no WebObjects or OPENSTEP applications running first):

```
cd $NEXT_ROOT

gunzip -c 3.5.1_Java_Patch_NT.tar.gz | gnutar xvfE -
```

6. Reboot your Windows NT system

On Windows NT, this patch replaces some of the files in the following directories. If you back up these directories before installing the patch, replacing them will return you to a "clean" installation:

- $NEXT_ROOT/NextDeveloper/Examples
- $NEXT_ROOT/NextDeveloper/Java
- $NEXT_ROOT/NextLibrary/Executables
- $NEXT_ROOT/NextLibrary/Frameworks
- $NEXT_ROOT/NextLibrary/Java

Installing WebObjects 3.5.1 Java Patch 2 on Solaris

1. Download the Solaris version of the patch from Apple's FTP site at ftp.info.apple.com. The file is located at:

```
/Apple_Support_Area/Apple_Software_Updates/MultiCountry/Enterprise/webobjects/patches/

3.5.1/3.5.1_Java_Patch_Solaris.tar.gz
```

2. Log in as root. If you're not sure how to log in as root, see your system administrator.

3. Type the following at the shell prompt (make sure that there are no WebObjects applications running first):

```
cd $NEXT_ROOT

gnutar xvf 2674_WebObjects_3.5.1_Java_Patch_Solaris.tar
```

4. Reboot your Solaris system

New Features

New features in WebObjects 3.5.1 Java Patch 2

Java VM arguments: You may now pass "command line" arguments to the Java Virtual Machine. This is particularly useful for increasing the memory allocation pool (the garbage collected heap), which defaults to a maximum size of 16 MB. You should increase the pool size if you receive

a java.lang.OutOfMemoryError exception.

Here is some sample code showing how to pass these arguments. Be sure to add the JavaVM framework to your project. In YourApplication_main.m, do something like this:

```
#import <JavaVM/NSJavaVirtualMachine.h>
int main(int argc, const char *argv[])
{
NSAutoreleasePool* shutUp=[NSAutoreleasePool new];
NSMutableDictionary* myArguments=[NSDictionary dictionaryWithObjectsAndKeys:
[NSNumber numberWithInt:30*1024*1024], @"NSJavaMinHeapSize",
[NSNumber numberWithInt:60*1024*1024], @"NSJavaMaxHeapSize",
nil];
[NSJavaVirtualMachine setDefaultVirtualMachineArguments:myArguments];
return WOApplicationMain(@"Application", argc, argv);
}
```

You can ignore the compiler warning about the unused AutoreleasePool variable.

For a complete list of arguments, refer to the NSJavaVirtualMachine.h header in the JavaVM framework.

Problems Fixed

Corrected in WebObjects 3.5.1 Java Patch 2

DecimalNumber: Several of the next.util.DecimalNumber arithmetic methods raised exceptions when called. These methods now work properly.

CalendarDate: The next.util.CalendarDate constructor CalendarDate(java.util.Date date) would sometimes return an incorrect date. This has been fixed.

NoSuchMethodError exceptions: WebObjects applications written in Java would occasionally raise a java.lang.NoSuchMethodError exception, when the method did in fact exist. This was caused by a race condition on the interaction between Objective C's reference counting and Java's garbage collection. This has been fixed. These exceptions could also be raised if a subclass of next.eo.CustomObject did not implement a default constructor (that is, an -init method with no parameters). Chained initializer methods would give the same result if some of the methods in the chain did not have Java equivalents. After installing this patch, a missing default constructor will generate a more meaningful error message.

Java string retain crashes: A problem was fixed where Java strings were garbage collected before WebObjects had a chance to retain them. The missing strings caused some applications to crash under heavy use.

Multiprocessor crashes on Solaris: Because of improper use of lock files, WebObjects 3.5.1 applications would sometimes crash on multiprocessor Solaris machines. This behavior is fixed in this patch.

Incorrect cloning behavior: Previously, custom Java objects did not correctly implement the Cloneable interface. With this patch installed, subclasses of NextObject and CustomObject should be cloneable.

DirectToWeb application crashing: The previous version of this patch for Windows NT caused crashes when launching a DirectToWeb application. This has been corrected in the current patch release.

EOEditingContext can now retain all referenced objects: EOEditingContext's weak references to objects caused problems with Java's multithreaded garbage collection. If you are writing an application which accesses the Enterprise Objects Framework from Java, you may encounter two problems:

- EOEditingContext's processing of an EO's deallocation notification is not thread safe
- An object that is no longer retained by your application but has not been deallocated may be refetched. However, the reference may be reestablished too late to prevent the object from being deallocated.

In order to solve this problem, we have made it possible for EOEditingContext to retain all of its objects. Two class methods have been added:

```
+ (void)setInstancesRetainRegisteredObjects:(BOOL)flag;

+ (BOOL)instancesRetainRegisteredObjects;
```

If instancesRetainRegisteredObjects is YES, newly created EOEditingContexts will retain any EOs that it is observing. The default value for this flag is YES if an application contains Java, and NO otherwise. Each EOEditingContext caches the value of this flag, so it is possible to switch from one state to the other midway through your application. Note that only newly created EOEditingContexts will be affected by the flag.

In order to collect the EOs, you must either deallocate the editing context, or call the new method:

```
- (void)reset;
```

on the editing context. Calling reset causes the editing context to forget and release all of the objects that it is watching, and makes all of those objects effectively unusable. You typically will not not have to do anything to a Java WebObjects application in order to be compatible with this new behavior. A session's defaultEditingContext will get collected when the session times out, releasing all of the EOs fetched by that session.

Corrected in EOF 2.2 Sybase Adaptor Patch

All parameters required for Sybase stored procedures
Apple reference # 2203081

PROBLEM:
If you did not supply all values when executing a Sybase stored procedure, the execution would fail with an exception like:

```
Feb 19 11:23:53 WOF_3_5_Sybase_Patch[1027] Caught exception:EOGeneralAdaptorException
Sybase: Server:unknown Procedure:NEXT_MOVIE_PRIMARY_KEY Line:0 Procedure NEXT_MOVIE_PRIMARY_KEY expects
parameter @A_MOVIE_ID, which was not supplied.
```

This happens even though A_MOVIE_ID is not required for the stored procedure.

RESOLUTION:
The Sybase adaptor no longer requires optional arguments to stored procedures.

Cannot fetch float-NSDecimalNumbers along with text columns
Apple reference # 2208497

PROBLEM:
If you have an attribute with external type float, and internal type NSDecimalNumber, it will not fetch properly if a text column is also in the fetch. The attribute will be blank.

RESOLUTION:
The Sybase adaptor now correctly fetches these attributes.

Corrected in EOF 2.2 ODBC Adaptor Patch

ODBC Adaptor cannot execute stored procedures with output parameters
Apple reference # 2208503

PROBLEM
The EOF 2.2 (WebObjects 3.5) version of ODBCEOAdaptor.framework introduced a bug which causes an error when using a stored procedure with an output parameter.

RESOLUTION
The ODBC adaptor now handles output parameters correctly.

ODBC adaptor leaks connections with Microsoft Access
Apple reference # 2209574

PROBLEM:
The EOF 2.2 (WOF 3.5) and earlier versions of ODBCEOAdaptor.framework did not release ODBC connections when using Microsoft Access (or any JET based data source) in order to work around a bug in the Microsoft odbcjt32.dll library; this bug caused a crash when SQLFreeConnect was called. The SQLFreeConnect bug was discovered in version 3.40.2829 of the DLL. Newer versions of the DLL (beyond 3.50) no longer exhibit the crashing problem.

RESOLUTION:
The patched version of this framework now checks the version of the DLL more carefully and allows SQLFreeConnect to be called unless the DLL version is 3.4X. The adaptor no longer leaks the ODBC Connection when running with fixed versions of odbcjt32.dll.

PCI Bus OPENSTEP Driver Overview

This article discusses a device driver for the OPENSTEP Mach operating system, versions 4.0 through 4.2.
This article has been archived and is no longer updated by Apple.
Driver: PCI Bus
Last Update: December 18, 1997

Availability Information

A version of this driver is on the OPENSTEP CD-ROM
No updated versions of this driver are available

Driver Name / Installer .pkg: PCIBus
Driver Type: System
Driver Scope: Generic-System

General Overview notes: This driver provides PCI Bus Services to the NEXTSTEP Operating System, PCI Device Drivers, and to Configure. NEXTSTEP requires this driver if the system contains a PCI Bus (either as PCI Slots or as an embedded Bus)

Driver Version Notes

4.00 - Released on OPENSTEP 4.0 User CD-ROM

* - Indicates information that is inclusive of the entire capability of this driver. Not all devices supported by this driver may include all features listed.
Published Date: Feb 18, 2012

OPENSTEP 4.2 Pentium II Incompatibilities

There have been two problems reported by customers using OPENSTEP for Mach, version 4.2, with some Pentium II systems. This document presents simple workarounds for both of these problems.

This article has been archived and is no longer updated by Apple.

Keyboard problems with Pentium II/400 systems

Pentium II systems with Intel's 440BX chipset running OPENSTEP Mach 4.2 will crash when certain keys, such as CAPS LOCK, are pressed. The problem can be solved by changing the keyboard mapping. In the Preferences application, click on the Localization Preferences (the flag icon) and select **NeXTUSA** from the list of keyboards. The problems does not affect systems with NeXTUSA keyboard mapping. If your system continues to crash, check your bios for an option with a name like **LEGACY USB SUPPORT**. Make sure this option is enabled.

Installation problems with Pentium II/400 systems

Some Pentium II/400 motherboards contain built-in power management systems that are incompatible with OPENSTEP 4.2's power management software. As a result, OPENSTEP will hang during the installation process as it tries to access power management. To install OPENSTEP Mach 4.2 on these systems, you will need to disable OPENSTEP's power management software.

At the boot: prompt that appears when you start up your OPENSTEP system, type:

"APM"="No"

You will need to type this again each time your system boots during the install process.

After the operating system is installed, add the following line to your \\private\\Drivers\\i386\\System.config\\instance0.table file:

"APM" = "No";

OPENSTEP should now boot without attempting to communicate with your computer's power management system.

Retain Counts Of Objects Loaded From .nib Files

This document explains how the Objective C retain and release cycle affects objects created by InterfaceBuilder under OPENSTEP 4.2.
This article has been archived and is no longer updated by Apple.

Q: What are the retain counts of objects loaded from .nib files? How do I make sure all of my interface objects are released when I'm finished with them?

A: All objects in a .nib file are created with internally consistent retain counts; that is, a view is retained by its superview or window and retains its subviews. The only exception to this is that objects in the top level of the nib are created with a retain count of 1. The "File's Owner" is expected to release each of these objects when they are no longer needed, and you should create outlets to these objects for this purpose. The top level of the nib consists of those objects that show up in Interface Builder's Instance view, excepting meta-objects like File's Owner and First Responder. The "release when closed" option in a window's inspector allows you to release windows for which you have no outlets. Do not use this option if you have an outlet to the window; release it manually instead. Remember that you are still responsible for releasing any objects that you retain in your custom objects' **init:** or **awakeFromNib:** methods.

WOMonitor Q & A

This article contains questions and answers about the WOMonitor application running under WebObjects 3.5.1 and WebObjects 4.
This article has been archived and is no longer updated by Apple.

Q: I used WOMonitor to open an application on another host. The messages on the other machine indicate that the process is running, but Monitor says it is not. How can I make Monitor report the application status correctly?

A: This problem occurs when more than one copy of WOMonitor is running on a subnet. The MonitorProxy process on your application server uses Apple's Distributed Objects technology to find and connect to an instance of WOMonitor. If more than one instance of WOMonitor is started on a subnet, a race condition is created, and the WOMonitor instance which responds first is the only one that receives notifications.

You can avoid this problem by specifying the host to which you wish MonitorProxy to report. When you launch MonitorProxy on your application server, use the syntax:

MonitorProxy -mhost *monitor_hostname*

MonitorProxy will then only try to connect to a Monitor process running on the specified host. If you are not sure to which Monitor process your application is connecting, MonitorProxy will report the hostname whenever a connection is made. Even if no hostname is specified, MonitorProxy will only look for WOMonitor processes within its own subnet.

You can also use the -mhost argument while starting your WebObjects application manually. Any processes you start from within Monitor will have their -mhost argument set automatically.

EOF and Multithreaded Applications

This document discusses multithreading under EOF 3.0 and previous releases.
This article has been archived and is no longer updated by Apple.

Q: Can I build a multi-threaded application using EOF?

A: **EOF 2.2** and previous releases are not thread-safe and EOF cannot be used in traditional multithreaded applications under WebObjects 3.5.1. Even if all of an application's EOF and database calls are contained in a single thread of a multithreaded application, there may be unpredictable failures as a result of this limitation.

For most applications, you can avoid the problem by using multiple processes instead of multiple threads. For each function you would otherwise assign to a new thread, start a new instance of a separate application process instead. You can use Apple's Distributed Objects (DO) technology to allow these applications to communicate with each other. You will still be able to use multithreading in those processes that do not involve EOF.

EOF 3.0 does support multithreading. In EOF 3.0, most objects support concurrent threads, except that only one active thread is allowed for each editing context and for each database context. This means that multiple requests can't be sent concurrently to a single database. Concurrenct, scalable database access is already available to WebObjects applications through running multiple instances. Multithreading now allows concurrency in most other EOF operations.

Complete information on multithreading under EOF 3.0 and WebObjects 4 is provided in the WebObjects 4 documentation.

NeXTSTEP 3.2 And Earlier CERT Security Advisories

This document contains the security advisories issued for NeXTSTEP versions 3.2 and previous.
This article has been archived and is no longer updated by Apple.

Disclaimer

This document pertains to the NeXTSTEP operating system (versions 3.2 and previous). Apple Computer no longer provides support for these products. This information is provided only as a convenience to our customers who have not yet upgraded their systems, and may not apply to OPENSTEP, WebObjects, or any other product of Apple Enterprise Software.

NeXTSTEP 2.x Advisories

==========

CA-91:20 CERT Advisory
October 22, 1991
/usr/ucb/rdist Vulnerability

The Computer Emergency Response Team/Coordination Center (CERT/CC) has
received information concerning a vulnerability in /usr/ucb/rdist (the
location of rdist may vary depending on the operating system). This
vulnerability is present in possibly all versions of rdist. Vendors
responding with patches are listed below. Additionally, some vendors
who do not include rdist in their operating systems are identified.
Operating systems from vendors not listed in either of the two categories
below will probably be affected and the CERT/CC has proposed a workaround
for those systems.

VENDORS THAT DO NOT SHIP rdist
(Note: Even though these vendors do not ship rdist, it may have been
added later (for example, by the system administrator). It is
also possible that vendors porting one of these operating systems
may have added rdist. In both cases corrective action must be taken.)

Patches may be obtained via anonymous ftp from ftp.uu.net or from local
Sun Answer Centers worldwide.

The CERT/CC is hopeful that other patches will be forthcoming. We will
be maintaining a status file, rdist-patch-status, on the cert.org
system. We will add patch availability information to this file as
it becomes known. The file is available via anonymous ftp to
cert.org and is found in pub/cert_advisories/rdist-patch-status.

All trademarks are the property of their respective holders.

I. Description

A security vulnerability exists in /usr/ucb/rdist that
can be used to gain unauthorized privileges. Under some
circumstances /usr/ucb/rdist can be used to create setuid
root programs.

II. Impact

Any user logged into the system can gain root access.

III. Solution

A. If available, install the appropriate patch provided by
your operating system vendor.

B. If no patch is available, restrict the use of /usr/ucb/rdist
by changing the permissions on the file.

chmod 711 /usr/ucb/rdist

The CERT/CC wishes to thank Casper Dik of the University of Amsterdam,
The Netherlands, for bringing this vulnerability to our attention.
We would also like to thank the vendors who have responded to this problem.

If you believe that your system has been compromised, contact CERT/CC via
telephone or e-mail.

NeXT rexd, /private/etc, Username me Vulnerabilities

The Computer Emergency Response Team/Coordination Center (CERT/CC) and NeXT Computer, Inc. have received information concerning three vulnerabilities in NeXT computers running various releases (see below) of NeXTstep software. For more information, please contact your authorized support center. If you are an authorized support provider, please contact NeXT through your normal channels.

Problem 1 DESCRIPTION: By default, rexd(8C) is enabled in NeXTstep versions 2.0 and 2.1. (Note that no NeXT software uses rexd.)

Problem 1 IMPACT: Leaving rexd enabled allows remote users to execute processes on a NeXT computer.

Problem 1 SOLUTION: Comment out or remove the rexd line in /etc/inetd.conf (unless you're using the remote execution facility), and either restart the computer or cause inetd to re-read it's configuration file, using:

kill -HUP <inetd pid>

Problem 2 DESCRIPTION: The /private/etc directory is shipped with group write permission enabled in all NeXTstep versions through and including 2.1.

Problem 2 IMPACT: Group write permission in /private/etc enables any user in the "wheel" group to modify files in the /private/etc directory.

Problem 2 SOLUTION: Turn off group write permission for the /private/etc directory, using the command:

chmod g-w /private/etc

or the equivalent operations from the Workspace Manager's Inspector panel.

Problem 3 DESCRIPTION: Username "me" is a member of the "wheel" group in all NeXTstep versions through and including 2.1.

Problem 3 IMPACT: Having username "me" in the "wheel" group enables "me" to use the su(8) command to become root (the user must still know the root password, however).

Problem 3 SOLUTION: Unless you have specific reason(s) not to, remove the user "me" from the wheel group.

The CERT/CC would like to thank NeXT Computer, Inc. for their response to this vulnerability. CERT/CC would also like to thank Fuat Baran for his technical assistance.

If you believe that your system has been compromised, contact CERT/CC
via telephone or e-mail.

CA-91:12 CERT Advisory
August 22, 1991
Trusted Hosts Configuration Vulnerability

The Computer Emergency Response Team/Coordination Center (CERT/CC) has
received information concerning a vulnerability in the configuration
of several system files. This advisory discusses a workaround since
there are no permanent patches available at this time.

This vulnerability is present in a very large number of UNIX-based
operating systems. Therefore, we recommend that ALL sites take the
corrective actions listed below.

I. DESCRIPTION:

The presence of a '-' as the first character in /etc/hosts.equiv,
/etc/hosts.lpd and .rhosts files may allow unauthorized access
to the system.

II. IMPACT:

Remote users can gain unauthorized root access to the system.

III. SOLUTION:

Rearrange the order of entries in the hosts.equiv, hosts.lpd,
and .rhosts files so that the first line does not contain
a leading '-' character.

Remove hosts.equiv, hosts.lpd, and .rhosts files containing only
entries beginning with a '-' character.

.rhosts files in ALL accounts, including root, bin, sys, news, etc.,
should be examined and modified as required. .rhosts files that
are not needed should be removed.

Please note that the CERT/CC strongly cautions sites about the

use of hosts.equiv and .rhosts files. We suggest that they NOT
be used unless absolutely necessary.

The CERT/CC wishes to thank Alan Marcum, NeXT Computer, for bringing
this security vulnerability to our attention. We would also like to
thank CIAC for their assistance in testing this vulnerability.

If you believe that your system has been compromised, contact CERT/CC via
telephone or e-mail.

CA-92:01 CERT Advisory
January 20, 1992
NeXTstep Configuration Vulnerability

The Computer Emergency Response Team/Coordination Center (CERT/CC)
has received information concerning a vulnerability in release 2 of
NeXTstep's NetInfo default configuration. This vulnerability will
be corrected in future versions of NeXTstep.

I. Description

By default, a NetInfo server process will provide information to
any machine that requests it.

II. Impact

Remote users can gain unauthorized access to the network's
administrative information such as the passwd file.

III. Solution

Ensure that the trusted_networks property of each NetInfo domain's
root NetInfo directory is set correctly, so that only those systems
which should be obtaining information from NetInfo are granted
access. The value for the trusted_networks property should be the
network numbers of the networks the server should trust.

Note that improperly setting trusted_networks can render your
network unusable.

Consult Chapter 16, "Security", of the "NeXT Network and System Administration" manual for release 2 for details on setting the trusted_networks property of the root NetInfo directory.

The CERT/CC wishes to thank NeXT Computer, Inc. for their cooperation in documenting and publicizing this security vulnerability.

If you believe that your system has been compromised, contact CERT/CC via telephone or e-mail.

Internet E-mail: cert@cert.org
Telephone: 412-268-7090 (24-hour hotline)

NeXTSTEP 3.x Advisories

CA-93:02a CERT Advisory
January 21, 1993
REVISION NOTICE: New Patch for NeXT NetInfo "_writers" Vulnerabilities

---

*** THIS IS A REVISED CERT ADVISORY ***
*** IT CONTAINS NEW INFORMATION ***

The CERT Coordination Center has received updated information from NeXT Computer, Inc. concerning vulnerabilities in the distributed printing facility of NeXT computers running all releases of NeXTSTEP software through NeXTSTEP Release 3.0. The online patch described in CERT Advisory CA-93:02 has been replaced with a new patch. The size and checksum information in this Advisory have been updated to reflect the new online patch.

For more information, please contact your authorized support center. If you are an authorized support provider, please contact NeXT through your normal channels.

I. Description

The default NetInfo "_writers" properties are configured to allow users to install printers and FAX modems and to export them to the network without requiring assistance from the system administrator. They also allow a user to configure other parts of the system, such as monitor screens, without requiring help from the system administrator. Vulnerabilities exist in this facility that could allow users to gain

unauthorized privileges on the system.

II. Impact

In the case of the "/printers" and the "/fax_modems" directories, the "_writers" property can permit users to obtain unauthorized root access to a system.

In the "/localconfig/screens" directory, the "_writers" property can potentially permit a user to deny normal login access to other users.

III. Solution

To close the vulnerabilities, remove the "_writers" properties from the "/printers", "/fax_modems", and "/localconfig/screens" directories in all NetInfo domains on the network, and from all immediate subdirectories of all "/printers", "/fax_modems", and "/localconfig/screens" directories. The "_writers" properties may be removed using any one of the following three methods:

A. As root, use the "niutil" command-line utility. For example, to remove the "_writers" property from the "/printers" directory:

/usr/bin/niutil -destroyprop . /printers _writers

B. Alternatively, use the NetInfoManager application: open the desired domain, open the appropriate directory, select the "_writers" property, choose the "Delete" command [Cmd-r] from the "Edit" menu, and save the directory.

C. To assist system administrators in editing their NetInfo domains, a shell script, "writersfix", is available via anonymous FTP from next.com (129.18.1.2):

Filename Size Checksum
-------- ---- --------
pub/Misc/Utilities/WritersFix.compressed 5600 25625 6

After transferring this file using BINARY transfer type, double-click on the file. A "WritersFix" directory will be created in your file system, containing the script ("writersfix") and some documentation ("WritersFix.rtf").

Consider removing "_writers" from other NetInfo directories as well (for example, "/locations"), noting the following trade-off between ease-of-use and security. By removing the "_writers" properties, the network and the computers on the network become more secure, but a system administrator's assistance is required where it previously was not required.

Please refer to the NeXTSTEP Network and System Administration manual for additional information on "_writers". Note that the subdirectories of the "/users" directory have "_writers_passwd" set to the user whose account is described by the directory. This is essential if users are to be able to change their own passwords, and this does not compromise system security.

The CERT Coordination Center wishes to thank Alan Marcum and Eric Larson of NeXT Computer, Inc. for notifying us about the existence of these vulnerabilities and for providing appropriate technical information.

If you believe that your system has been compromised, contact the CERT Coordination Center or your representative in FIRST (Forum of Incident Response and Security Teams).

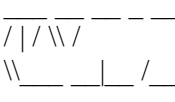
The Computer Incident Advisory Capability



ADVISORY NOTICE

Automated Scanning of Network Vulnerabilities

September 30, 1993 1100 PDT Number D-25

PROBLEM: Automated attacks on networked computers.
PLATFORM: All systems supporting TCP/IP networking.
DAMAGE: Unauthorized access to information and computer resources.
SOLUTION: Examine machines for vulnerabilities detailed below and apply fixes as needed.

Critical Information about Automated Network Scanning Software

CIAC has learned that software allowing automated scanning of networked computers for security vulnerabilities was recently made publicly available on the Internet. The software package, known as ISS or Internet Security Scanner, will interrogate all computers within a specified IP address range, determining the security posture of each with respect to several common system vulnerabilities. The software was designed as a security tool for system and network administrators. However, given its wide distribution and ability to scan remote networks, CIAC feels that it is likely ISS will also be used to locate vulnerable hosts for malicious reasons.

While none of the vulnerabilities ISS checks for are new, their aggregation into a widely available automated tool represents a higher level of threat to networked machines. CIAC has analyzed the operation of the program and strongly recommends that administrators take this opportunity to re-examine systems for the vulnerabilities described below.

Also detailed below are available security tools that may assist in the detection and prevention of malicious use of ISS. Finally, common symptoms of an ISS attack are outlined to allow detection of malicious use.

ISS Vulnerabilities

The following vulnerabilities are tested for by the ISS tool. Administrators should verify the state of their systems and perform corrective actions as indicated.

Default Accounts The accounts "guest" and "bbs", if they exist, should have non-trivial passwords. If login access to these accounts is not needed, they should be disabled by placing a "*" in the password field and the string "/bin/false" in the shell field in /etc/passwd. See the system manual entry for "passwd" for more information on changing passwords and disabling accounts.

For example, the /etc/passwd entry for a disabled guest account should resemble the following:

guest:*:2311:50:Guest User:/home/guest:/bin/false

lp Account The account "lp", if it exists, should not allow logins. It should be disabled by placing a "*" in the password field and the string "/bin/false" in the shell field in /etc/passwd.

Decode Alias Mail aliases for decode and uudecode should be disabled on UNIX systems. If the file /etc/aliases contains entries for these programs, they should be disabled by placing a "#" at the beginning of the line and then executing the command "newaliases". Consult the manual page for "aliases" for more information on UNIX mail aliases.

A disabled decode alias should appear as follows:

decode: "|/usr/bin/uudecode"

Sendmail The sendmail commands "wiz" and "debug" should be

disabled. This may be verified by executing the

following commands:

% telnet hostname 25
220 host Sendmail 5.65 ready at Wed, 29 Sep 93 20:28:46 PDT
wiz
You wascal wabbit! Wandering wizards won't win!
(or 500 Command unrecognized)
quit

% telnet hostname 25
220 host Sendmail 5.65 ready at Wed, 29 Sep 93 20:28:46 PDT
debug
500 Command unrecognized
quit

If the "wiz" command returns "Please pass, oh mighty wizard", your system is vulnerable to attack. The command should be disabled by adding a line to the sendmail.cf configuration file containing the string:

OW*

If the "debug" command responds with the string "200 Debug set", you should immediately obtain a newer version of sendmail software from your vendor.

Anonymous FTP Anonymous FTP allows users without accounts to have restricted access to certain directories on the system. The availability of anonymous FTP on a given system may be determined by executing the following commands:

```
% ftp hostname
Connected to hostname.
220 host FTP server ready.
Name (localhost:jdoe): anonymous
530 User anonymous unknown.
Login failed.
```

The above results indicate that anonymous FTP is not enabled. If the system instead replies with the string "331 Guest login ok" and then prompts for a

password, anonymous FTP access is enabled.

The configuration of systems allowing anonymous FTP should be checked carefully, as improperly configured FTP servers are frequently attacked. Refer to CIAC Bulletin D-19 for more information.

NIS SunOS 4.x machines using NIS are vulnerable unless the patch 100482 has been installed. See CIAC Bulletin C-25 for more information regarding this patch.

NFS Filesystems exported under NFS should be mountable only by a restricted set of hosts. The UNIX "showmount" command will display the filesystems exported by a given host:

```
% /usr/etc/showmount -e hostname
export list for hostname:
/usr hosta:hostb:hostc
/usr/local (everyone)
```

The above output indicates that this NFS server is exporting two partitions: /usr, which can be mounted by hosta, hostb, and hostc; and /usr/local which can be mounted by anyone. In this case, access to the /usr/local partition should be restricted. Consult the system manual entry for "exports" or "NFS" for more information.

rusers The UNIX rusers command displays information about accounts currently active on a remote system. This may provide an attacker with account names or other information useful in mounting an attack. To check for the availability of rusers information on a particular machine, execute the following command:

```
% rusers -l hostname
hostname: RPC: Program not registered
```

If the above example had instead generated a list of user names and login information, a rusers server is running on the host. The server may be disabled by placing a "#" at the beginning of the appropriate line in the file /etc/inetd.conf and then sending the SIGHUP signal to the inetd process. For example, a disabled rusers entry might appear as follows:

```
#rusersd/2 dgram rpc/udp wait root /usr/etc/rusersd rusersd
```

rexd The UNIX remote execution server rexd provides only minimal authentication and is easily subverted. It should be disabled by placing a "#" at the beginning of the rexd line in the file /etc/inetd.conf and then sending the SIGHUP signal to the inetd process. The disabled entry should resemble the following:

```
#rexd/1 stream rpc/tcp wait root /usr/etc/rexd rexd
```

Available Tools

There are several available security tools that may be used to prevent or detect malicious use of ISS. They include the following:

SPI SPI, the Security Profile Inspector, will detect the system vulnerabilities described above, as well as many others. U.S. Government agencies interested in

obtaining SPI should send E-mail to spi@cheetah.llnl.gov or call (510) 422-3881 for more information.

COPS The COPS security tool will also detect the vulnerabilities described above. It is available via anonymous FTP from ftp.cert.org in the directory /pub/tools/cops/1.04.

ISS Running ISS on your systems will provide you with the same information an attacker would obtain, allowing you to correct vulnerabilities before they can be exploited. Note that the current version of the software is known to function poorly on some operating systems. If you should have difficulty using the software, please contact CIAC for assistance. ISS may be obtained via anonymous FTP from ftp.uu.net in the directory

/usenet/comp.sources.misc/volume39/iss.

TCP Wrappers Access to most UNIX network services can be more closely controlled using software known as a TCP wrapper. The wrapper provides additional access control and flexible logging features that may assist in both the prevention and detection of network attacks. This software is available via anonymous FTP from ftp.win.tue.nl in the file /pub/security/tcp_wrappers_6.0.shar.Z

Detecting an ISS Attack

Given the wide distribution of the ISS tool, CIAC feels that remote attacks are likely to occur. Such attacks can cause system warnings to be generated that may prove useful in tracking down the source of the attack. The most probable indicator of an ISS attack is a mail message sent to "postmaster" on the scanned system similar to the following:

From: Mailer-Daemon@hostname (Mail Delivery Subsystem)
Subject: Returned mail: Unable to deliver mail
Message-Id: <9309291633.AB04591@>
To: Postmaster@hostname

----- No message was collected -----

If you should receive such a message, it is likely that your machine and others on your network have been scanned for vulnerabilities. You should immediately contact your computer security officer or CIAC for assistance in assessing the damage and taking corrective action.

For additional information or assistance, please contact CIAC at

(510) 423-9878 or send E-mail to ciac@llnl.gov. FAX messages to (510) 423-8002.

PLEASE NOTE: Many users outside of the DOE and ESnet computing communities receive CIAC bulletins. If you are not part of these communities, please contact your agency's response team to report incidents. Your agency's team will coordinate with CIAC. The Forum of Incident Response and Security Teams (FIRST) is a world-wide organization. A list of FIRST member organizations and their constituencies can be obtained by sending email to docserver@first.org with an empty subject line and a message body containing the line: send first-contacts.

NeXT SECURITY BULLETIN: NeXT-94:001-sendmail, 16 February 94

PROBLEM:
A security vulnerability has been identified in all versions of NEXTSTEP up to and including Release 3.2. This vulnerability, described in CERT advisories CA-93:16 and CA-93:16a, may allow unauthorized remote or authorized local users to gain unauthorized privileges. All sendmail recipient machines within a domain could potentially be vulnerable.

SOLUTION:
NeXT has corrected this vulnerability and provided a patch containing new binaries for both NeXT and Intel-based computers running NEXTSTEP Release 3.1 or Release 3.2.

Note: At the present time, NeXT has no plans to make a patch available for releases of NEXTSTEP prior to Release 3.1.

Published Date: Feb 18, 2012

A/UX 2.0.1: Internet Forwarder Bug

I'm trying to get an Internet forwarder running under A/UX 2.0.1. I have configured several systems the same way, with no luck. I've tried using a Macintosh IIfx, a Macintosh IIci and a Macintosh IIx, each with 2 rev K EtherTalk cards. The other systems on the networks include a Macintosh IIx on each network and a Decstation 2100 and a MacBlitz card on the 192.33.20 network.

Here are the procedures I've been using in my attempts to bring up the forwarder:

1) Install the cards into the system.

2) Do a newconfig nfs and answer "n" to the YP client prompt.

3) Configure IP & broadcast addresses & netmasks for each card
so /etc/NETADDRS file look like:

0 192.33.20.1 192.33.20.255 255.255.255.0
1 134.69.50.1 134.69.50.255 255.255.255.0

4) Set up my /etc/hosts file to include hosts on both sides of the
router as follows:

0x7F.0x00.0x00.0x01 loop lo loo localhost
192.33.20.1 jabberwock #ae0 host reference
134.69.50.1 jabberwock1 #ae1 host reference
192.33.20.2 manticore
134.69.50.4 fredsys
192.33.20.200 dextra # decstation 2100
192.33.20.201 blitzoid # macblitz 50/8

5) Restart the system and verify that the following daemons
are running:

/etc/portmap
/etc/inted
/etc/in.routed
/etc/nfsd 4 (4 of these)
/etc/biod 4 (4 of these)
/etc/rpc.lockd
/etc/rpc.statd

6) From system "manticore", which has an Internet address of
192.33.20.2, a broadcast address of 192.33.20.255 and a netmask of
255.255.255.0, I can ping jabberwock successfully on both sides
(192.33.20.1 and 134.69.50.1). Additionally, I can rlogin to both sides
of jabberwock (the /etc/hosts file contains EXACTLY the same info as
jabberwock's) using "rlogin jabberwock" and "rlogin jabberwock1".

7) From system "fredsys", that has an Internet address of 134.69.50.4,
a broadcast address of 134.69.50.255, and a netmask of 255.255.255.0, I
can access both sides of jabberwock the same as I could from manticore.
Again, the /etc/hosts file is identical to jabberwock's.

8) Neither ping nor Telnet nor rlogin is successful from manticore to
?redsys or vice versa. The /etc/hosts files are the same on all three
?f these machines. All of the addresses match up as they should.

9) Verify the cables and terminations; check the interfaces
with an ifconfig ae0 on all three machines and an ifconfig ae1 on
jabberwock. All addresses and interfaces show up as they should, but

to no avail.

10) At this point, I can't Telnet, ftp, ping or rlogin to fredsys from any system on the 192.33.20 network except jabberwock.

11) From jabberwock, I can ping all of the other systems on both nets. I can rlogin, etc. all of the other systems. I just can't cross the barrier from one net to the other.

Any suggestions?

This article has been archived and is no longer updated by Apple.

With the above configuration, we have been able to reproduce your problem. On an A/UX 2.0.1 Internet forwarder/router, the host "manticore" on network 192.33.20 CAN'T talk to the host "fredsys" on network 134.69 via A/UX 2.0.1 Internet forwarder host "jabberwock".

With the same configuration, but with the Internet forwarder/router (jabberwock) running A/UX 2.0, the problem goes away. Hosts ("manticore" and "fredsys" in this case for example) on different networks via A/UX 2.0 router CAN talk to each other.

NeXTSTEP Graphics and PostScript Q&A

This document pertains to the NeXTSTEP operating system, which is no longer a supported product of Apple Computer. This information is provided only as a convenience to our customers who have not yet upgraded their systems, and may not apply to OPENSTEP, WebObjects, or any other product of Apple Enterprise Software. Some questions in this Q&A document may not apply to version 3.3 or to any given specific version of NeXTSTEP.

This article has been archived and is no longer updated by Apple.

Q: Why does NeXTSTEP 3.3 show poor graphics performance when I use a PCI video card?

A: In order to work around a hardware problem involving the Intel 824x0 PCI host-bus chip, the Intel824X0 PCI driver supplied with NEXTSTEP version 3.3 disables Write-Posting--a performance feature--in this controller chip. Without this workaround, users of bus-mastering drivers, including PCI SCSI and ethernet drivers, would experience intermittent system crashes with possible resulting data corruption. Note that this is a problem with the controller chip, not with NEXTSTEP. Version 3.3 of NEXTSTEP simply implements a workaround to this operating-system independent hardware problem.

The tradeoff for this increased robustness is lower performance than would be possible if write-posting could be safely enabled. Given the potential for data loss which exists with this chip, NeXT strongly recommends that users of PCI bus mastering devices accept the lower performance this workaround causes. Though it is possible to achieve higher performance even for bus-mastering devices by disabling the Intel824X0 driver, this is not a recommended or supported system configuration because of the increased risk of system crashes and data loss.

If the PCI bus is only being used for video, however, and no PCI bus-mastering devices are installed, NeXT knows of no adverse impact which will result from removing the Intel824x0 driver, and substantially improved video performance may result. However, note that use of PCI devices with this driver disabled is not supported even for non bus-mastering devices and, if done, is at your own risk. In addition, if you chose to disable the Intel824x0 driver, you must ensure that if PCI bus-mastering devices are later installed in the system the Intel824x0 driver will be re-enabled at that time or an increased risk of data corruption will result.

The PCI chipset bug only occurs in the A0 stepping of the Intel 824x0 series of chipset. This bug was corrected in the A1 stepping of the chip which went into production around September of '94. Unfortunately, this chip is usually soldered directly to the motherboard; therefore, you should contact your PC vendor if you require servicing.

A new driver has been released for the Intel 824x0 chipset which automatically recognizes the flawed 824x0 chipset on your system. It will only disable write-posting if it detects a flawed chipset. See NeXTanswers document 1790_Intel_824X0_PCI_Chipset_Driver_Overview.rtf for more information.

Q: Will either of your color products (NeXTdimension or NeXTstation Color) support color lookup tables? What about NEXTSTEP for Intel Processors?

A: The NeXTdimension supports full 32-bit ªrealº color<approximately 16 million colors can be displayed at any given pixel. The hardware is configured as 8 bits of each color component: red, green, blue and alpha. The alpha component may be used to record relative transparency for any given pixel.

The NeXTstation Color supports 16-bit color<4 bits each: R, G, B and alpha. This allows 4096 different colors to be displayed at any given pixel. In addition, the WindowServer uses dithering to make the images look more realistic. Neither machine supports color-mapped color.

NEXTSTEP for Intel Processors follows the same guidelines as the black hardware does. At this time, the maximum color resolution supported on Intel hardware is 16-bit color. (Release 3.0)

Q: When using the color machines can I turn the color ªoffº (so that it will run in 2-bit mode) to increase performance?

A: No. The i860 processor on the NeXTdimension board speeds up the color operations to give performance equivalent to a monochrome cube with a MegaPixel display. (Release 3.0)

Q: If I read a TIFF file into the NeXT which contains a color palette, does the sofware understand the palette correctly or does it ignore that information as in 1.0?

A: Although NeXTStep does not, in general, support palette-based imaging, there is limited support in Release 2.0 and later. TIFF files which contain 8-bit palettes of 24-bit color values are read in and converted to 32-bit color images; other palettes-based images are not understood. (Release 3.0)

Q: My timed entry does not seem to be occurring when I use **DPSPeekEvent()**.

A: Timed entries are executed only when **getNextEvent:** or **DPSGetEvent()** is called. They will not be "triggered" by **DPSPeekEvent()**. A timed entry does not interrupt the current process; it will be executed the next time between events.

Q: How much movement triggers a mouse-moved event?

A: Any change in the screen coordinates of the cursor (even one pixel) creates a mouse-moved or mouse-dragged event. But see the documentation for **DPSSetTracking()**; event coalescing may be influencing your perception of how this works.

Q: How can I send a PostScript file directly to the WindowServer?

A: You should usually use NXImage. However, if that's not appropriate in your situation use the following code snippet. **Warning**: Do not use **PSRun()**, because your application may not work with -NXHost since the file you specified may not exist on the other machine.

```
int SendFileToPS(const char *fileName)
{
NXStream *st;
char *addr;
int len, maxlen;

st = NXMapFile(fileName, NX_READONLY);
if (st) {
NXGetMemoryBuffer(st, &addr, &len, &maxlen);
DPSWriteData(DPSGetCurrentContext(), addr, len);
NXCloseMemory(st, NX_FREEBUFFER);
return 0;
} else
return -1;
}
```

Q: If I fill a circle using PostScript, then stroke it with a different color using the default linewidth of 1, not all of the pixels get covered at the edges. I thought a linewidth of 0 could cause this problem, but a linewidth of 1 shouldn't! Drawing applications such as Draw.app demonstrate the same problem: Create a circle filled with black and outlined with white, using a line thickness of 1. You'll notice stray black pixels around the edges. What's going on here? How can this problem be avoided?

A: PostScript scanning should normally cause any non-zero linewidth to eliminate the stray pixels in the above scenarios. However, PostScript also has a "stroke adjustment" feature which, when turned on, tries to create lines of uniform thickness on low-resolution output devices (such as displays). This causes the above problems to appear<a line of width 1 drawn on a path might fail to fully cover the pixels on the edges of a fill done on the same path. By default, stroke adjustment is enabled for displays and disabled for printers.

Given this, developers of drawing and other applications should look into turning off stroke adjustment when displaying graphic objects created/manipulated by users in documents. This can be accomplished with

```
false setstrokeadjust
```

The previous strokeadjust value should be restored once the graphics are drawn; this can be done via gsave/grestore or by explicitly remembering the previous value:

```
currentstrokeadjust
false setstrokeadjust
... drawing code ...
```

setstrokeadjust

You can read more about the setstrokeadjust and currentstrokeadjust operators in section 6.5 of the PostScript Language Reference Manual 2nd edition (the level 2 red book).

Q: While drawing in a window performing animation, I also want to be able to accept events, such as a key stroke. But the animation must continue if no event occurs. Timed entries are not a solution because the animation must be continuous and smooth and is being drawn too fast for the granularity that timed entries provide.

A: Use DPSPeekEvent() to catch events while not blocking.

Q: There seems to be a problem with compositing. Using the CompositeLab in /NextDeveloper/Examples on a 2-bit screen, set the following parameters and use the SOVER operation:

Source gray=1 opacity=0.3 (white mostly transparent source)
Dest gray=0.8 opacity=1 (light gray opaque destination)

You will see that the result is the same color as the destination. Thus the 30% coverage from the white source is having no effect at all! Now change the source opacity to 0; this causes no change in the result. What's going on here?

A: The behavior is correct. Assume the case where the source is all white and is 33% opaque. Say the destination is 66% white and opaque. (This assures that we are using exact pixel values with no dithering.) The SOVER formula is:

sourceColor * sourceOpacity + destColor * (1 - sourceOpacity)

which for our case reduces to

1 * 1/3 + 2/3 * 2/3 = 7/9

which is rounded to 6/9, given that compositing only works on a per-pixel basis. Changing the opacity all the way down to 0 simply changes the resulting pixel to 6/9, thus no color change occurs.

Now using the parameters in the question

Source gray=1 opacity=0.3 (white mostly transparent source)
Dest gray=0.8 opacity=1 (light gray opaque destination)

We see that there are some source pixels with opacity of 0, and a few with opacity of 1/3. Source color is 1 in all cases. There are some dest pixels with gray of 1 and others with 2/3; opacity is 1 in both cases.

Thus every resulting pixel is computed from one of four formulas:

sourceColor * sourceOpacity + destColor * (1 - sourceOpacity)
1 * 0 + 1 * (1 - 0) = 1
1 * 1/3 + 1 * (1 -1/3) = 1
1 * 0 + 2/3 * (1 -0) = 2/3
1 * 1/3 + 2/3 * (1 -1/3) = 7/9

Thus the result is equal to the dest color in all cases.

If you wish to composite in a more accurate fashion, you can use 8-bit deep grayscale windows. However, this will use up a lot more memory and is probably not worth it.

Q: What do errors like the following mean?

DPS client library error while writing to connection DPS context c18c data -102

A: The error reporter is basically printing out the elements of data passed in the exception initiated by NX_RAISE(). Usually the header file that defines the exception codes tells what data items are also passed. Since this is a DPS client library error, we look through <dpsclient/dpsclient.h> for a write error exception code:

dps_err_select, dps_err_read and dps_err_write signal communication
errors in the connection. The OS return code is passed in arg1;
arg2 is unused.

In interpreting the dpsclient error message, the first data item is always the DPS context in which the error occurred. The second item corresponds to arg1. Note that any arg2 referred to in the exception code description doesn't get passed from the DPSErrorFunc into the NXRaise exception scheme. Luckily, there aren't any DPS errors where arg2 is essential info.

So, for the above error, the c18c is a DPS context and the -102 is a Mach return code. The Mach codes happen to be defined in <sys/message.h>. By the way, negative numbers in about the -100 to -1000 range tend to be Mach error return codes.

Q: I'm using NXImage to display a PostScript or TIFF file. When I display it on a color system, the image doesn't look right<there are large black areas.

A: Probably your image has transparency in it. The image was rendered into an NXImage and then composited onto the screen using **NX_COPY**. Since **NX_COPY** produces an exact copy of the bits from the source, transparent areas in the NXImage were copied onto the screen. On the monochrome MegaPixel display, these transparent areas expose to white, to emulate the way a sheet of paper might behave. NeXT's color devices act more like video devices, and they expose to black.

In order to avoid exposing the underlying device's representation of transparent, you should fill in the background and composite the NXImage using **NX_SOVER**:

```
- drawSelf:(NXRect *)rects :(int)rectCount
{
NXPoint pt = {0.0, 0.0};

NXSetColor(NX_COLORWHITE);
NXRectFill(rects);
[anImage composite: NX_SOVER toPoint: &pt];
return self;
}
```

Valid for 2.0, 3.0

Q: In my application I am reading in an NXImage. A nil is never returned, even if I

read in a bogus file. Is this a bug? Here is my code:

```
id myNXImage = [NXImage alloc];
if ([myNXImage initFromFile: "dummyName.tiff"] == nil)
{
/* this is never getting called! */
fprintf(stderr,"dummyName.tiff doesn't exist!\\n");
}
```

A: This is not a bug. The **initFromFile:** method is lazy and does not catch *all* the errors that might happen when loading an image. Your application should be prepared to check for errors later on down the line either through delegation or by checking the **composite:** or **lockFocus** return values. If you wish, you can force the image to be rendered immediately:

```
id myNXImage = [[NXImage alloc] initFromFile: filename];
if ([myNXImage lockFocus])
[image unlockFocus];
else
fprintf(stderr,"%s doesn't exist\\n", filename);
```

Although this behavior might seem confusing it allows for more optimal performance: the image isn't rendered into the cache until it is needed. Rendering a large or complex file can be slow<particularly for a complex EPS file.

Note: Another good approach for determining whether an image can be successfully rendered is the NXImage delegate method **imageDidNotDraw:inRect:**. If you have assigned a delegate for the image and implemented this method, it gets called when compositing fails for whatever reason. See the documentation on NXImage for more information about this method. Also note that this method of delegation may be the only way to catch a drawing error for an image which is being "handed" to the AppKit<an icon on a button, for example.

There is a known bug in Release 2 where **imageDidNotDraw:inRect:** fails to be called when encountering an error from within the method **composite:toPoint:**. This bug can be avoided by using the NXImage method **composite:fromRect:toPoint:**. This bug has been fixed in Release 3.

Valid for 2.0, 3.0

Q: I'm writing an application which can open either EPS or TIFF images using the NXImage class. How can I determine what kind of file I've opened without hacking the file name?

A: You can use the isKindOf: method from the Object class:

```
id myNXImage, myImageRep;

myNXImage = [[NXImage alloc] initFromFile: fileName];
myImageRep = [myNXImage lastRepresentation];
if ([myImageRep isKindOf: [NXBitmapImageRep class]])
{
/* then I'm a TIFF file! */
}
else if ([myImageRep isKindOf: [NXEPSImageRep class]])
{
```

```
/* then I'm an EPS file! */
}
```

The key here is that the NXImage instance itself does not understand EPS or TIFF information per se. NXImage manages the *representation* classes (one NXImage may have multiple representations) which do understand EPS and TIFF information.

Of course, it is reasonable to extract this information from the fileName as well. The following code snippet can be used to do this:

```
char *fileType = rindex(fileName, '.');

if (!fileType)
{
/* then I'm not an appropriate file! */
}
else if (!strcmp(fileType, ".tiff"))
{
/* then I'm a TIFF file! */;
}
else if (!strcmp(fileType, ".eps"))
{
/* then I'm an EPS file! */
}
```

Valid for 2.0, 3.0

Q: My application is a simple paint program. The user opens a TIFF image, then scribbles into it, and finally saves the new image as a TIFF file. However, the changes made by the user aren't saved into the TIFF file<it contains the original image. Why?

A: This occurs if you open the TIFF file like this:

```
image = [[NXImage alloc] initFromFile:fileName];
```

NXImage will have two representations<the file, and the cache. NXImage will treat the cache as a transitory image, and the file as its "best representation." The cache is the off-screen window to which the user's scribbles are drawn. When asked to write out the image, NXImage writes out its best representation of the image<which is the actual TIFF file residing on disk<thus ignoring completely the changes made to the image. To get around this you must fake out NXImage by forcing the cache to be the best representation of the image.

The following code snippet illustrates what you must do:

```
/* When the user opens the image */
rep = [[NXBitmapImageRep alloc] initFromFile:fileName];
[rep getSize:&imageSize];

image = [[NXImage alloc] initSize:&imageSize];

if ([image useCacheWithDepth:d] && [image lockFocus]) {
[rep draw];
[image unlockFocus];
}
```

```
[rep free];
```

This code sample initialized an NXBitmapImageRep from the file containing the opened image. The NXImage is initialized from this representation. Now the NXImage does not have a file which can serve as its best representation<it only has the cache. Thus when you tell NXImage to **writeTIFF:** the cache with all of the user's scribbles is written out properly.

Valid for 1.0, 2.0, 3.0

Q: I have allocated an instance of NXImage and an instance of NXBitmapImageRep. I then tell the NXImage to use the rep instance, like this:

```
NXRect originalSize;
id myRep, myImage;
int bitsPerPixel;

myRep = [[NXBitmapImageRep alloc] initFromFile: filename];
[myRep getSize: &originalSize];
myImage = [[NXImage alloc] initSize: &originalSize];
[myImage useRepresentation: myRep];
```

Then, later in my application I query the rep instance (as follows) and the query fails because myRep is nil! Why is this?

```
bitsPerPixel = [myRep bitsPerPixel]; /* this fails -- myRep is nil ! */
```

A: This is not a bug. Once you have ªgivenº the NXBitmapImageRep instance to NXImage (by calling useRepresentation:) then the NXImage "owns" that rep and can do what it wishes with it. (This is also true for any class of rep instance, not just NXBitmapImageRep) What the NXimage typically does is to turn that representation into an NXCachedImageRep and then free the NXBitmapImageRep. To prevent this behavior do a setDataRetained:YES on the NXImage instance. The setDataRetained: method defaults to NO. The NXImage then does not free the NXBitmapImageRep. For example, to correct the above example, add the following line prior to calling useRepresentation:

```
[myImage setDataRetained:YES];
```

Valid for 2.0, 3.0

Q: I want my application to periodically and automatically perform an operation. For instance, I want to save a backup file every 5 minutes, or I want to create a blinking cursor. How do I go about doing that? Should I use timer events?

A: What you actually want is a timed entry. The Display PostScript routines **DPSAddTimedEntry**() and **DPSRemoveTimedEntry**() are used to start and stop timed entries. These functions are described in the Next Developer Documentation in the DPS section. You install a timed entry to run at a specific interval and give a handler function which will be called at each interval. What actually happens is that for each cycle of the event loop, the application checks to see if there are any timed entries which are due. If so, then the handler function is called, thus "cutting" in line in front of any other events. Timed entries are ªcoalescedº in a sense because the next occurrence of a timed entry is set when

the current entry is processed. There is never more than one occurrence of a timed entry waiting to run and since timed entries aren't inserted into the event queue, you don't have to worry about timed entries overflowing the queue.

Timer events are not the correct thing to use in this instance, because they are intended to be used in modal loops. Each application has an event queue, where pending events are waiting to be processed. Each application has a main loop which simply polls for events, and then reacts accordingly. Modal loops allow you to create a loop which is secondary to the application loop, and supersedes it for a short time. You use modal loops when you have received one event and are then waiting for another which then terminates the modal loop. The modal loop must ensure that it will continue to get a continuous stream of events, and it does this with timer events. You use timer events in a modal loop in case the user is doing something that is not generating events (such as holding down the mouse button, and not moving it).

There are several programming examples that use timed entries. If you want a simple example of a timed entry, see the **BusyBox** example under **/NextDeveloper/Examples/AppKit**. The **ClockView** class there uses a timed entry to animate the movement of the hands. (Tip: It can be very helpful to drag **/NextDeveloper/Examples** into your Digital Librarian and index it. Another useful Librarian target is **/usr/include**.)

Valid for 1.0, 2.0, 3.0

Q: I've installed a timed entry to run at a specific interval in my application. I receive a timed entry and my application goes off to process it. For some reason the processing takes longer than the interval between the timed entries. The result is that a second entry happens before the application finishes processing the previous entry. Will the second entry be queued or does it interrupt?

For Releases 1 and 2:
A: Neither. The timed entry interval specifies the time that passes between the time the timed entry function returns and the time it is called again. Thus, if you have an interval of 10 seconds, and your timed entry function takes 5 seconds to execute, your function is called every 15 seconds.

Sometimes this might be a bad thing; it is then the responsibility of your timed entry function to adjust the interval. For instance, in the ClockView class (/NextDeveloper/Examples/Clock under 1.0 and /NextDeveloper/Examples/BusyBox under 2.0), the function that gets called at the top of the minute stops the timed entry and starts it again with an new interval equivalent to the number of seconds left to the next top of the minute. This prevents the clock from ªslowing downº and missing minutes when the system is slow. (It however does not bother with this in the seconds mode; missing a second or two here and there is okay.)

The Animator class shows how to create an ªadjustingº timed entry, which is a bit more complex. The Animator class is used by /NextDeveloper/Examples/BreakApp under Release 1 and /NextDeveloper/Examples/ToolInspector under Release 2.

For Release 3:
A: In Release 3, the system tries to call the function with the requested periodicity, regardless of how long the function takes to execute. However, if the function takes longer than the period to execute, the timed entries do not try to "catch up" to make up for the missed call(s).

In Releases 1 and 2, timed entries were accurate to only 15 ms. In Release 3, they are accurate to ~1 ms.

Sendmail Questions

Q: Why is sendmail timing out to my local mailhost?

Q: Why do I get "connection timed out" messages while trying to connect to my local mailhost. When I log in to the mailhost, it seems lightly loaded?

Q: Why is mail taking so long to deliver locally?

A: There are probably several possible answers to these questions. Here is one of them.

Mail gets queued up in /usr/spool/mqueue using two different files for each piece of mail. One file is the header information for the mail, and the other file is the body of the message. The directory /usr/spool/mqueue, like all directories, is simply a file that contains a listing of filenames and their associated inodes that are contained in the directory. The size of a directory is usually around 1 or 2 kilobytes. The more files you have in a directory and the longer the names of the files, the larger the size of the directory file is. The size of the directory file never decreases.

Whenever a file is created the system must open up the directory file and write some information into it. The larger the directory file is, the longer it takes to read through it and add the new entry. The same thing is true for deleting files.

If you have a mail server that deals with a lot of traffic and something causes the mail to get backed up in the queue, the directory file can grow very large (50+ KB) storing the names of the backed up mail. Even after clearing the entire queue, the size of the directory file remains the same, and creating and destroying files in that directory starts taking a significant amount of time. In fact, the mail server can become so slow that connections to it start timing out even though the machine seems to be very responsive.

The only solution is to create a new mqueue directory:

1. Find the incoming sendmail process and kill it.

```
% ps auxw | grep sendmail
root 206 0.0 0.8 1.55M 312K ? S 0:04 -accepting connections (sendmail)
% kill <PID> # PID is 206 in the above example
```

2. Wait for the outgoing sendmail processes to finish.

```
% ps auxw | grep sendmail
```

You can keep running the above command until all of the outgoing sendmail processes

have died or you can go ahead and kill them all. Sendmail should be tolerant of getting killed.

3. Move /usr/spool/mqueue to /usr/spool/mqueue.old and create a new mqueue

```
% cd /usr/spool
% mv mqueue mqueue.old
% mkdir mqueue
```

5. Move all of the files from mqueue.old into the new mqueue directory

```
% mv mqueue.old/* mqueue
```

6. Remove old mqueue directory

```
% rmdir mqueue.old
```

6. Restart sendmail

```
% /usr/lib/sendmail -bd -q30m
```

Valid for 1.0, 2.0, 3.0

Q: How do I cause mail to be automatically forwarded to destinations outside our local network through some outside service?

A: You'll need to make some minor changes to your mailhost's **sendmail.cf** file. The sendmail configuration file, **/etc/sendmail/sendmail.cf** is either a link to **sendmail.mailhost.cf** or is some variant of the mailhost configuration. You edit this file on your mailhost<the machine which is responsible for forwarding mail.

Look for the following lines near the top of the file (in the default **sendmail.mailhost.cf**, they start at line 30):

```
# If you want to use a relay mailer, examine ruleset 0. There are some
# rules that need to be uncommented
DMuucp

# major relay host: use the $M mailer to send mail to other domains
# To have mail automatically forwarded to other domains, you should
# replace this with the name of your major relay host.
DR mail-relay
CR mail-relay
```

The line

```
DMuucp
```

tells sendmail that mail destined for a machine off the local network should be forwarded using the ªuucpº mailer < i.e., using the UNIX UUCP facility. The lines

```
DR mail-relay
CR mail-relay
```

indicate that the machine called **mail-relay** is the forwarding host. Change these three lines to reflect your actual situation. Typically, **uucp** is the appropriate mailer if you're not on the

Internet. Either replace **mail-relay** with the name of your UUCP partner, or ensure that **mail-relay** is a host alias of that partner. (Note that if you make **mail-relay** be an alias for that partner and you're using UUCP as the relay mail mechanism, you have to modify the UUCP configuration files to reflect this alias.)

If you look at the comments which begin the excerpt included above, you see a note regarding uncommenting some lines in ªruleset 0.º Look for the following lines in **sendmail.cf** (at line 323 in the default **sendmail.mailhost.cf**):

```
# If you want to pass all other explicit domain names up the ladder
# to our forwarder then uncomment the following line.
#R$*<@$*.$+>$* $#$M $@$R $:$1<@$2.$3>$4 user@any.domain
# and comment out this one.
R$*<@$+.$->$* $#ddn $@ $2.$3 $:$1<@$2.$3>$4 user@any.domain
```

These lines describe how to forward non-local mail. In the default file for a mailhost, such mail is forwarded using the **ddn** mailer (i.e., over the Internet). We want to change that, to use the mail specified above, in the **DM** line. To do this, uncomment the third line and comment out the fifth line:

```
# If you want to pass all other explicit domain names up the ladder
# to our forwarder then uncomment the following line.
R$*<@$*.$+>$* $#$M $@$R $:$1<@$2.$3>$4 user@any.domain
# and comment out this one.
#R$*<@$+.$->$* $#ddn $@ $2.$3 $:$1<@$2.$3>$4 user@any.domain
```

WARNING: Be *very* careful when you modify a sendmail configuration file. As you might notice, the syntax is arcane and cryptic, and the ªrewriting rulesº in the configuration file are intricate.

Valid for 1.0, 2.0 ,3.0, 3.1

Q: My Release 3.0 client or mailhost machines are extremely slow. When I look at the processes, I see that there are several hung sendmail processes, and mail isn't being sent. My mailhost is a Sun (or a third party PC gateway program such as Banyan Vines or CCMAIL).

A: There are timing problems within the sendmail code on Release 3.0 that cause mail traversing Sun mailhosts (and certain mail gateways such as Banyan Vines and CCMAIL) to hang and take up excessive process time. The symptoms usually are:

· Machine is extremely slow.

· The sendmail process is using too much CPU time, or many sendmail processes are running, but never complete.

· Mail is not being delivered to the mailhost, or to the gateway.

The solution is as follows:

· Rename the file **/usr/lib/sendmail** to **/usr/lib/sendmail.30**.

· Copy **/usr/lib/sendmail.old** to **/usr/lib/sendmail**. The file **sendmail.old** is NeXT's Release 2 version of sendmail, and alleviates the timing errors.

Perform this procedure on Release 3.0 clients and/or any NeXT mailhosts which are forwarding mail to one of the above gateways.

Make sure the permissions are set correctly on the sendmail file:

-r-sr-x--x 1 root wheel 81920 Jul 21 14:48 sendmail*

Valid for 3.0 **only**

NFS Questions

Q: When I have a Sun Solaris 2.4 system as an NFS client and a NEXTSTEP 3.3 system as the NFS server, the access starts out very slow. What casues this and is there a way to speed up the access time?

A: This problem is caused by a change in the Solaris NFS code in the 2.4 release. The new version of NFS READDIR in the Solaris 2.4 release trys to request more than 1024 bytes of directory data (this gains faster reponse from the NFS servers that support the larger size). The NEXTSTEP NFS server (and other NFS servers which are based on older NFS source code) fail to repond to this request. Sun Solaris will retransmit the **READDIR** requests and eventually will dynamically change the **rsize** and **wsize** values for the mount to smaller values. You may verify this on the Sun with **nfsstat -m** command. In about 2 to 5 minutes the **rsize** and **wsize** will be reduced and the **READDIR** requests to the Next start working!

To workaround this problem set the **rsize** and **wsize** for the **mount** entries on a Solaris 2.4 NFS client to 1024 for all mounts from NEXTSTEP NFS servers.

Q: I logged in on an NFS client, and the Workspace Manager indicated that my home directory (which it knows correctly) is not a directory, and it can't change to the directory. Yet, there are no errors during (verbose) boot with the mount. My home directory is on a server. Everything looks correct in NetInfo. What's going on?

A: Check the current date on the client. Apparently, if it's extremely screwed up (e.g., something before the epoch, Thu Jan 1 00:00:00 1970), the NFS accesses don't function correctly.

Q: Why is the performance of my file server so poor? The load is high and rpc.mountd is taking up large chunks of CPU time.

A: There is a file called /etc/rmtab, which contains statistics about remotes mounts. See the man page rmtab(5) for details. When an NFS client crashes, it does not remove its entry in this file and so as more NFS clients crash, the file /etc/rmtab on the file server grows without bound. Eventually things break or slow down severely. Notable symptoms are:

· The file /etc/rmtab is large<there should only be one line for each NFS client mounting a

file system.

· High %CPU (e.g., higher than any other process) value as shown by ps -aux:

```
nfsserver% ps -aux | grep mount
USER PID %CPU %MEM VSIZE RSIZE TT STAT TIME COMMAND
root 276 19.6 1.4 1.23M 224K ? S 0:00 rpc.mountd
...
```

· High load values on the server immediately following multiuser boot.

· Home directories not mounting properly.

The fix is as follows:

1) Boot the machine in single-user mode.
2) Empty the file /etc/rmtab (e.g., cat /dev/null > /etc/rmtab).
3) Reboot.

This solves the problem.

Q: I've exported a directory from a file server. Some machines (perhaps) can mount that directory successfully, others cannot, and receive a message like:

```
Access denied for server:/directory
```

The directory on the server is exported for universal access (e.g., nidump exports . reports something like

```
/directory -ro
```

granting any machine read-only access rights). What's going on?

A: What's likely wrong here is that the server doesn't know about the client. Check the appropriate hosts databases (the machines directory in NetInfo, for example) in all applicable domains. The client must appear in there somewhere.

This typically will not be seen in a two-level NetInfo hierarchy, but could be seen in a three-level hierarchy.

This feature is an important part of NFS security, and is not a bug.

NIS/YP Questions

Q: My NIS (Yellow Pages) database doesn't seem to be examined correctly. One symptom, for instance, is that ypbind is running fine and ypcat works great, but ~user doesn't work.

A: This is likely caused by the lack of a + line in the UNIX *flat file*. If something isn't found in NetInfo, the system looks in the appropriate UNIX flat file. If that file is to "include" the appropriate NIS map, it must have a proper + line in it. At the point where NIS might be examined, it's as if the NetInfo database *did not exist*, and *was not referenced*.

A + line in the NetInfo database is irrelevant.

NeXTSTEP Programming Kits Q&A

Disclaimer

This document pertains to the NeXTSTEP operating system, which is no longer a supported product of Apple Computer. This information is provided only as a convenience to our customers who have not yet upgraded their systems, and may not apply to OPENSTEP, WebObjects, or any other product of Apple Enterprise Software. Some questions in this Q&A document may not apply to version 3.3 or to any other specific version of NeXTSTEP. Some or all of the programming interfaces referred to in this document may no longer be supported in any current product.
This article has been archived and is no longer updated by Apple.

SoundKit Questions

Q: Why doesn't SoundView's *setReductionFactor:* work in Release 3?

A: There is a known bug in the SoundView's **setSound:** method which resets the reductionFactor even if you are explicitly setting it yourself. If you wish to use your own reductionFactor, you need to call **setReductionFactor:** after each call to **setSound:**.

The SoundEditor example released in 3.0 uses **setReductionFactor:**, but it doesn't work correctly because of this bug.

A point of confusion is that the reduction methods<setReduction and reduction<have been removed from the API for 3.0, but the reductionFactor methods<setReductionFactor and setReduction<are still part of the API.

Valid for 3.0, 3.1

Q: How can I determine a Sound's duration?

A: Send the Sound the sampleCount and samplingRate methods (if necessary) and divide the former number by the latter.

Q: How can I get Sounds to repeat one after the other, or the same one multiple times?

A: There are several approaches; however, none are guaranteed to work in all possible situations.

1) You can compute the duration of each sound just before you play it (following the approach in the answer to the first question). Set up a timed entry (see documentation on DPSAddTimedEntry) that occurs at a time equal to the sound's duration plus any desired delay between playings. When you get this timed entry, you tell the next Sound to play, and so forth.

2) If you don't require an Application event loop, you can reliably chain sounds together using the Sound library C functions. See the example file /NextDeveloper/Examples/Sound/chaintest.c, and the README file in the same directory. You are advised to use the SNDNotificationFun approach, as in this example, and to avoid the SNDWait() function.

3) If you require an Application with an event loop (the normal case), you might have

success using the SoundKit delegation method didPlay:. Create an object that is the Sound's delegate, or use an existing object. Provide it with these methods:

```
int sndCtr;

- init {
[mySound setDelegate:self]; /* mySound is the Sound to be looped */
sndCtr = 1;
}

- playIt {
[mySound play];
}

- didPlay:sender {
if (sndCtr++ < NUMTIMES)
[self playIt]; /* play it NUMTIMES in a row. Alternately, use some other terminating condition, or trigger other Sounds here */
}
```

This approach sometimes causes problems in the playback, however, particularly if the user interrupts the playing with an event such as a mouse-down. You'll have to try it for your specific case and see whether it works.

4) If none of these approaches is suitable, the workaround is to create a new Sound composed of multiple copies of the desired sound(s), using the SoundKit's copy/paste functionality. You can do this splicing programmatically with the insertSamples:at: method, or manually by using the SoundEditor example.

5) As a final option, you can combine the chaintest strategy with the SoundKit example above. Override Sound's "play" method and directly enqueue the soundstruct with SNDStartPlaying, giving it your own special SNDNotificationFun to do the chaining as in chaintest. The drawback of this approach is that you cannot safely send the delegate a soundDidPlay: message when the repeat count runs out.

Valid for 1.0, 2.0, 3.0

Q: I am porting my sound driver program from Release 2 to 3. But the kernel header file snd_msgs.h is no longer available in Release 3. What can I do to get a handle on the error codes returned by the SNDDRIVER functions?

A: You can include the following code in your program to provide for error handling:

```
#import <sound/sounderror.h> /* for SNDSoundError() */

#ifndef SNDDRIVER_NO_ERROR
#define SNDDRIVER_NO_ERROR 100 // non-error ack.
#define SNDDRIVER_BAD_PORT 101 // message sent to wrong port
#define SNDDRIVER_BAD_MSG 102 // unknown message id
#define SNDDRIVER_BAD_PARM 103 // bad parameter list in message
#define SNDDRIVER_NO_MEMORY 104 // can't allocate memory (record)
#define SNDDRIVER_PORT_BUSY 105 // access req'd to existing excl access port
#define SNDDRIVER_NOT_OWNER 106 // must be owner to do this
#define SNDDRIVER_BAD_CHAN 107 // dsp channel hasn't been inited
#define SNDDRIVER_SEARCH 108 // couldn't find requested resource
#define SNDDRIVER_NODATA 109 // can't send data commands to dsp in this mode
```

```
#define SNDDRIVER_NOPAGER 110 // can't allocate from external pager (record).
#define SNDDRIVER_NOTALIGNED 111 // bad data alignment.
#define SNDDRIVER_BAD_HOST_PRIV 112 // bad host privilege port passed.
#define SNDDRIVER_BAD_PROTO 113 // can't do requested operation in cur protocol
#define SNDDRIVER_MAX_ERROR 113
#endif

static char *snddriver_error_list[] = {
"sound success",
"sound message sent to wrong port",
"unknown sound message id",
"bad parameter list in sound message",
"can't allocate memory for recording",
"sound service in use",
"sound service requires ownership",
"DSP channel not initialized",
"can't find requested sound resource",
"bad DSP mode for sending data commands",
"external pager support not implemented",
"sound data not properly aligned",
"bad host provilege port passed",
"can't do requested operation in extant DSP protocol"
};

/*
* Error code to string conversion
*/
extern char *mach_error_string();
char *snddriver_error_string(int error)
{
if (error <= 0)
return mach_error_string(error);
else if (error >= SNDDRIVER_NO_ERROR && error <= SNDDRIVER_MAX_ERROR)
return snddriver_error_list[error-SNDDRIVER_NO_ERROR];
else
return SNDSoundError(error);
}

void snddriver_error(char *msg,int error)
{
char *errtype;
if (error <= 0)
errtype = "mach";
else if (error >= SNDDRIVER_NO_ERROR && error <= SNDDRIVER_MAX_ERROR)
errtype = "snddriver";
else
errtype = "sound";
fprintf(stderr,"%s\\n\\t%s error:%s\\n",msg,errtype,snddriver_error_string(error));
}
```

NetInfo Kit Questions

Q: I've read the release notes about the NetInfoKit (NIKit). Is there additional information about these objects and how to use them?

A: The only documentation that is currently available are the on-line Release Notes on 2.0 and whatever you can glean from the .h files. As you saw from those notes, it provides you with a rough overview of the objects available in the NIKit, but doesn't provide you with

any reference material. Through this document, we hope to shed some light on the NIKit objects, how to use them, and for what purpose.

Feedback for these objects would be greatly appreciated by the folks in engineering. Please send your feedback to bug_next@next.com.

NIDomain object
The first object, the NIDomain object, was created so that the other objects could have something through which to communicate to the NIKit database. The panel objects (like NIOpenPanel) use NIDomain to set and retrieve data from the NetInfo database. This object is the most likely one to change in future releases. You probably won't use NIDomain directly in your application, since the panel objects provide a higher level interface to it.

NIDomainPanel Object
The NIDomainPanel object is essentially a browser. It browses through the domain hierarchy, and displays it (much like the file system browser). To use the NIDomainPanel you should follow these steps:

- new
returns an id for the new instance of the NIDomainPanel.
- runModal
this runs a modal loop which exits when the user clicks ok or cancel
- exitFlags
returns whether the user clicked ok or cancel
- domain
returns the name of the domain that the user has selected.

The other methods are primarily there in case you wish to override them and provide some special functionality. Most useful are **cancel**, **ok** and **domain**.

NIOpenPanel Object
The next object, NIOpenPanel is a sub class of NIDomainPanel. It is used to display and select a particular directory from a list of its peers inside of any NetInfo domain in the hierarchy. It's analogous to the OpenPanel for filesystems. NIOpenPanel consists of the domain browser (which it inherits from the NIDomainPanel), buttons and a scrolling list of directories. You create an NIOpenPanel the same way in which you create a NIDomainPanel: using **new** and **runModal**. The other really interesting methods in NIOpenPanel are the **directory** and **setDirectoryPath** methods which you can use to programmatically browse to the directory path that you want from inside of the domains, or ask the NIOpenPanel where it currently is browsed to.

NISavePanel Object
NISavePanel is a subclass of NIOpenPanel, and is used to assist in saving changes to an open directory in a particular domain. NISavePanel is very much like NIOpenPanel, but with some additional functionality. It provides three different **runModal** routines. **runModal** is the one which you will use most frequently. It will start such that the browser is displaying your current domain. **runModalWithString** runs a modal loop, and starts up

such that the browser is displaying the domain which is passed in through "initialValue". **runModalwithUneditableString** is the same except for the fact that the directory is uneditable. It is used this way inside the NetManager and UserManager where the name of the directory is a fundamental property of the machine or user being edited and cannot be changed on the fly while performing a Save To.

NILoginPanel Object

And finally the NILoginPanel. This is probably the object for which you will have the most use. The login panel is used to verify (authenticate) a user's identification. You can either rely on the user id and password that are stored in the NI database, or you can use your own. There are three **runModal** methods in this object as well:

- (BOOL)runModal:sender inDomain:(void *) domainID;
This runs the login dialog modally with the default user "root".

- (BOOL)runModal:sender withUser:(char *)userName inDomain:(void *)domainID withString:(const char *)whatWarning allowChange:(BOOL)disableUser;
This runs the login dialog modally with the user as specified. You can change the message displayed on the panel by using the withString argument. Also, this method allows the user to
edit the default user name.

- (BOOL)runModalwithValidation:sender withUser:(const char *)userName inDomain:(void *) domainID withString:(const char *)whatWarning allowChange:(BOOL)enableUser;
This runs the login dialog modally as the previous method. However, this one requires validation.
With this modal method you can provide your own password validation scheme. You use this
in conjunction with the NILoginPanelDelegate's **authenticateUser** method.

At this point there is no example code from which you can learn to use these objects wisely (or at all). For examples about how these NIKit objects look and for an idea of how they can be put to good use, you can look at the system administration tools in /NextAdmin. Most of them use the NIKit. Future changes in the NIKit will be made to better support these applications.

Valid for 2.0, 3.0

DBKit Questions

Q: I put together a Database Kit program using InterfaceBuilder and it works fine in InterfaceBuilder's test mode. When I compile this program and try to run it independently, an attention panel opens and indicates: "Cannot load Adaptor: Oracle Adaptor." Why?

Q: I build a Database Kit application and add **libdbkit_s.a** to the Libraries directory in ProjectBuilder. Why do I still get the following error message in the console:

```
Error loading /NextLibrary/Adaptors/SybaseAdaptor.adaptor/SybaseAdaptor
rld(): Undefined symbols:
```

In GDB, the undefined symbols are reported as _sys_nerr, _sys_errlist, and _send.

A: In order for a Database Kit application to work, adaptor code must be made available to it. There are two ways to achieve this:

1) Hard-link an adaptor into your application. To do this, simply drag the adaptor you want onto the Libraries icon in ProjectBuilder's Files window. The adaptors provided by NeXT are located in **/NextLibrary/Adaptors**.

2) Dynamically load the adaptor code. To do this, you need to create a file in your project directory called **Makefile.preamble**, which contains the following line:

```
OTHER_LDFLAGS = -u libdbkit_s -u libNeXT_s -u libsys_s
```

Q: What are the pros and cons of dynamically loading adaptor code?

A:
Pros
You can write generic tools, without knowing which database they will be run against. Your application gets the latest and greatest version of adaptors, in case NeXT revises them.

Cons
Dynamically loading an adaptor slows down program startup (often by several seconds)

Q: How can I get hold of the DBBinder used by my application's DBDatabase object?

A: You can't. If you want to use DBBinders in your application, you have to create them yourself. See **/NextDeveloper/Examples/DatabaseKit/Binder** for some usage of a DBBinder.

Q: How can I view the SQL queries generated in my program?

A: You can trace the actual SQL queries generated by the Database Kit by having an object becoming the DBDatabase object's delegate. The delegate object must implement the **db:willEvaluateString:usingBinder:** method. For more details, see **Controller.m** in the **/NextDeveloper/Examples/DatabaseKit/AddressBook** example.

Q: What are the pros and cons of using one DBModule vs. two to implement insert/save in the case of a one-to-many relationship?

A: In case of 2 DBModules (one for the master table and one for the detail table), you don't have to find the detail fetchgroup programmatically. You can insert a new record into the detail module by simply connecting a button to the detail module **insertNewRecord:** method. When saving, you need to save the master module first, then save the detail module. See the **/NextDeveloper/Examples/DatabaseKit/OracleDemo** for an example of two modules.

In case of a single DBModule (representing the master table), you need to find the detail fetchgroup programmatically in order to insert a new record. However, you need to do only *one* save operation on the module, and it saves all changes from the root fetchgroup as well as the detail fetchgroup(s). The module save operation groups both fetchgroup saves as a single transaction.

Q: How can I synchronize a master DBModule with a detail DBModule ?

A: Just drag and drop the one-to-many relationship in the master DBModule onto the icon of the detail DBModule in the nib file. See **/NextDeveloper/Examples/DatabaseKit/OracleDemo** for more details on how to synchronize two modules.

Q: How do I connect a property of my table to a PopUpList object? I've tried connecting an attribute of my table to the PopUpList but nothing happens. The PopUpList still shows item 1, item 2, etc.

A: PopUpList connections can be made only to a field "x.y.z" where x is an entity, y is a one-to-one relationship, and z is a leaf-node field that is either a number or a string. For example, if you connect the attribute "name" from your Employee table to the PopUp, it only shows item1, item 2, etc. However, if you connect "Employee.Department.name", it shows all the names in the department.

Q: Which Application Kit objects are supported by the Database Kit?

A: The Database Kit contains various subclasses of DBAssociation designed to connect DBFetchGroups to certain Application Kit objects. Those Application Kit objects are:

TextField
Slider
Matrix of Cells or FormCells
NXBrowser
Text Object in a ScrollView
Button connected to a PopUp menu

Note:
Radio buttons and switches are not supported. See the RadioAssociation MiniExample for a workaround (radio buttons only).

Q: The model that I built with DBModeler shows only the views and tables that I own. How can I access all the views and tables in an Oracle database?

A: By default, DBModeler loads only those tables and views owned by the current user. However, you can extend the list of users for whom tables and views should be loaded. To do so, add the following to the defaults database<for example, to show the tables and views owned by the users David, Joe, Tony:

localhost> dwrite OracleAdaptor OracleTableOwners "'DAVID','JOE','TONY'"

The user names have to be quoted and the current user name has to be included as well. In order to load system tables, you can simply add the users 'SYSTEM' and 'SYS'. You can modify or change your list by using **dremove**, then **dwrite**. See the UNIX man pages for more information on **dread**, **dremove**, and **dwrite**. Note that this answer does not cover issues about access rights to system tables. Please refer to the Oracle manuals for further information.

Q: What should I do on my NEXTSTEP system in order to use my Oracle server with the Database Kit?

A: You need to do the following:
On the server side:

1) Check if oraserv is running.

2) Check if you have a file oratab under /etc. The oratab file has entries of the following format:

$ORACLE_SID:$ORACLE_HOME:<N|Y>
The entries in that file must match the entries you give to DBModeler. See item#4d. Specify "Y" so that the server can be started with dbstart at system boot up time.

On the client side:

3) Look at your /etc/services file:
a) Check with the Oracle DBA to verify that the database is using socket 1525 (this is the default). Enter the following into /etc/services:

orasrv 1525/tcp oracle

b) Niload the Oracle services. Be sure to check with the Oracle DBA to verify that the database is using socket 1525 (this is the default). If you want your entire network of NeXT machines to see the server, niload the entry in the root NetInfo domain on the master NetInfo server.

localhost> **su**
localhost# **niload services / </etc/services**

4) To access an Oracle server over TCP/IP.

a) Launch /NextDeveloper/Apps/DBModeler.app

b) Select the OracleAdaptor from the Preferences menu item.

c) Choose "New Model."

d) For the Oracle login panel, enter the appropriate information:

server id: <whatever ORACLE_SID is set to>
host: <server machine name>
login: <user login>
password: <user password>

e) Save the model in **~/Library/Databases**, **/LocalLibrary/Databases**, **/NextLibrary/Databases** or **/usr/local/Databases**. These are the default search paths that InterfaceBuilder uses to load models into the DatabaseKit palette.

f) From InterfaceBuilder, drag a DBModule palette (the lower left icon in the DBKit palette view) into the IB Objects suitcase. This operation creates an instance of DBModule. You can look at your model via the DBModule inspector and start creating your DBKit application.

Q: Why can I no longer load the Sybase/Oracle adaptor after I run **make install** on my DBKit application?

A: The problem is that **make install** does a complete stripping of the executable to save space by default. In order to force Makefile to recognize that DBKit adaptors need to be dynamically loaded, you must add the following line to your **Makefile.postamble**:

APP_STRIP_OPTS = $(DYLD_APP_STRIP_OPTS)

See also /NextDeveloper/Makefiles/apps/app.make for a full description of the rules.

Q: When I try to statically link an adaptor into my MAB [Multiple Architecture Binary] Database Kit application using NextStep Release 3.1 or 3.2, I get the following error at compilation time:

ld: for architecture i386
ld: warning /NextLibrary/Adaptors/SybaseAdaptor.adaptor/SybaseAdaptor cputype (6, architecture m68k) does not match cputype (7) for specified -arch flag: i386 (file not loaded)

ld: for architecture m68k
ld: warning /NextLibrary/Adaptors/SybaseAdaptor.adaptor/SybaseAdaptor cputype (7, architecture i386) does not match cputype (6) for specified -arch flag: m68k (file not loaded)

How can I overcome these errors?

A: The adaptors provided with Release 3.1 or 3.2 are for one single architecture type only. For example, to build a MAB Sybase Adaptor file, you need to do the following:

· Get the 2 versions of the file **SybaseAdaptor** from the directory **/NextLibrary/Adaptors/SybaseAdaptor.adaptor** . For convenience, we rename them respectively **SybaseAdaptor_m68k** and **SybaseAdaptor_i386** in this example.
· Use the Unix command **lipo(1)** to create a MAB adaptor file from these 2 input files. For example:

myhost> lipo **SybaseAdaptor_m68k SybaseAdaptor_i386** -create -output **~/Library/Adaptors/SybaseAdaptor_MAB**

Now, you can hard link the adaptor into your MAB application. See also adaptor_linking.rtf.

Q: When I use the DBBinder evaluateString method to issue SELECT statements with an Oracle adaptor and retrieve data from my tables, the LONG column values are always returned as NULL. What is going wrong?

A: This is a known problem with the Oracle Adaptor in Releases 3.1 and 3.2. If you use

InterfaceBuilder and the DBModule fetch mechanism to retrieve data from LONG columns, it works properly. However, if you must use a binder object, you need to set up your properly list before calling the binder evaluateString. For example, if you have a table **A** with two columns **attr1** and **attr2**, where **attr1** is defined as integer, and **attr2** is defined as LONG, you need to create a property list that includes these two attributes, and initialize the binder accordingly. See the code snippet below as an example:

```
/* Initialize the binder and set it up */
DBBinder *binder = [[DBBinder alloc] init];
List *resultList = [[List alloc] init];
List *props = [[List alloc]init];

[binder setDatabase:myDatabase];
[binder setContainer:(id)resultList];

/* This is the workaround to the LONG datatype problem.
You must create a property list that contains all the
columns you want to select in your query before doing
the evaluateString. */
myTable = [myDatabase entityNamed:"A"];
[props addObject:[myTable propertyNamed:"attr1"]];
[props addObject:[fooTable propertyNamed:"attr2"]];
[binder setProperties:props];
result = [binder evaluateString:"select * from A"];

/* Do the rest of the work, such as fetching data,
freeing the binder and other resources after they are used, etc...*/
```

Q: Whenever I try to run **make profile** against my DBKit application, I get the following error:

```
cc -g -pg -O -Wall -DPROFILE -I./sym -arch i386 -ObjC -u libdbkit_s -u libNeXT_s -u libsys_s -sectcreate __ICON
__header OrderByTest.iconheader -segprot __ICON r r -sectcreate __ICON app
/usr/lib/NextStep/Workspace.app/application.tiff -o OrderByTest.profile/OrderByTest i386_profile_obj/OrderBy.o
i386_profile_obj/OrderByTest_main.o /NextLibrary/Adaptors/OracleAdaptor.adaptor/OracleAdaptor -ldbkit_s -lMedia_s -
lNeXT_s
ld: multiple definitions of symbol _exit
/lib/gcrt0.o definition of _exit in section (__TEXT,__text)
/lib/libsys_s.a(exit.o) definition of absolute _exit (value 0x50023f6)
*** Exit 1
Stop.
*** Exit 1
Stop.
```

What's happening?

A: Since profiling with bundles is not possible, you have to hard-link the DBKit adaptor you are using instead of dynamically loading it. For example, if you are using the Sybase Adaptor, you can hard-link it by adding the following line to your Makefile.preamble:

```
OTHER_OFILES = /NextLibrary/Adaptors/SybaseAdaptor.adaptor/SybaseAdaptor
```

Since you are no longer using dynamic loading, you also need to remove all of the -u commands in the LDFLAGS or OTHER_LDFLAGS option from your Makefile.preamble. For example, you need to delete this line from your Makefile.preamble:

```
OTHER_LDFLAGS = -u libdbkit_s -u libNeXT_s -u libsys_s
```

Now, you should be able to link and profile your application as desired. Note that if you want to profile DBKit, you need to link with the profiled version of DBKit, **libdbkit_p.a**, instead of **libdbkit_s.a**.

Valid for 3.0, 3.1

Q: I have put together a DBKit program with InterfaceBuilder and it uses DBModule to make connections between UI Objects and Record List. The DBModule is the textDelegate for the instance TextFields. I type some characters into a TextField, and, without pressing Return or Tab, I clicked the Save button (or chose the Save menu command). I subsequently discovered that the data in the very last TextField was not saved. Why?

A: The problem is that **textWillEnd:endChar:** is not invoked when you click a button or choose a menu command without pressing Return, Tab or back Tab first. You need the following code to get the lastly-edited value in the action method of the Button or Menu item.

```
- save: sender
{
id association = [dbModule editingAssociation];
id fetchGroup = [association fetchGroup];
[fetchGroup takeValueFromAssociation: association];
...
...
}
```

Q: In DBModeler, how do I describe a multiple-field unique key for an entity? If a single property serves as a unique key for a record<such as "employee id" might serve for an employees entity<I can select the Unique Key box in the DBModeler Inspector. But how do I create a multiple-field key for a "sales" entity in which to identify a sale uniquely, I have to look at seller, buyer, and date?

A: You may check the "Unique Key" box in as many properties of an entity as you like. This is interpreted as a multiple-field key.

Q: I am having a problem when I have only one record in a tableview. I cannot delete it using the DBModule method **deleteRecord:**. When I print out the generated SQL, I only see the following:
BEGIN TRANSACTION
COMMIT TRANSACTION
What's happening?

A: This is a bug introduced in Release 3.2. To work around this problem, you should send a **saveModifications** message to the DBRecordList which matches your DBModule to save the deletion to the database. For example, you can use the following code snippet as a wrapper around your delete method:

```
delete:sender
{
[dbModule deleteRecord:sender];
#ifdef BUG_WORKAROUND
```

```
[[[dbModule rootFetchGroup] recordList] saveModifications];
#endif
return self;
}
```

Note that this bug will be fixed in a future release, thus you may need to put a #ifdef around the workaround. Also, the same code snippet can run on Release 3.1 without any effect.

Valid for 3.2 only

Q: What are the known problems with DBKit?

A: These are the known problems:

Sorting Records

Sorting cannot be set from InterfaceBuilder. To specify a sort order, you use the DBRecordList method **addRetrieveOrder:**(DBRetrieveOrder)*anOrder* **for:**(id<DBProperties>)*aProperty***;**

A problem is that when you reset the DBRecordList using the **setProperties:** method, it also resets the sort order. Both DBFetchGroup and DBModule send a **setProperties:** message before fetching. So, if you try to interpose in the fetch with a custom object, set up the sort order, then fetch, the sort order won't be set anymore. The way to get around this is to be the DBFetchGroup's delegate and respond to the **fetchGroupWillFetch:** message, and to set up the sort order on the sender's DBRecordList.

See the **/NextDeveloper/Examples/DatabaseKit/TableView** which changes the sort order every time you move the columns of the DBTableView.

Sybase Adaptor
· The adaptor doesn't infer relationships from the database.
· The adaptor doesn't read in system tables.

Oracle Adaptor
· The adaptor doesn't handle sequence numbers.
· The adaptor doesn't read relationships from the database.
· The adaptor doesn't handle catalog of databases.

DBModeler
· DBModeler doesn't import relationship information from the database into the dbmodels.

Keys
· You cannot update the primary key of your record. The only way is to delete the old record, do a save operation, and insert the new record with the modified key.

Qualifiers
· In general, all expressions in the qualifier need to be attributes or relationships coming from the qualifier's root entity. Only one-to-one relationship attributes can be built into the

qualifier. There is a known bug however with fetching with a qualifier built from one-to-one relationship attributes. As a workaround, you need to invoke the DBFetchGroup method **addExpression:** or create an expression implicitly using a connection to the File Owner. This bug has been fixed in Release 3.2.

· To qualify records fetched from a detail DBFetchGroup in case of a one-to-many relationship, you must use custom code. See the **/NextDeveloper/Examples/DatabaseKit/AssociationSybase** or **AssociationOracle** for more details.

· There is a known problem with parenthesizing qualifiers. As a workaround, follow the steps below:

Given the following qualifier:

```
[qual1 initForEntity:e FromDescription:"name = 'SMITH' OR name = 'JONES'"];
[qual1 addDescription:" AND age < 10 OR age > 20"];
```

This generates an SQL with no parenthesized grouping:

```
"name = 'SMITH' OR name = 'JONES' age < 10 OR age > 20"
```

The workaround is as follows:

```
[qual1 initForEntity:e FromDescription:"name = 'SMITH' OR name = 'JONES'"];
[qual2 initForEntity:e FromDescription:"(%@) AND (age < 10 OR age > 20)", qual1];
```

or more generally:

```
[qual1 initForEntity:e FromDescription:"name = 'SMITH' OR name = 'JONES'"];
[qual2 initForEntity:e FromDescription:"age < 10 OR age > 20"];
[qual3 initForEntity:e FromDescription:"(%@) AND (%@)", qual1, qual2];
```

These qualifiers then generate:

```
"(name = 'SMITH' OR name = 'JONES') AND (age < 10 OR age > 20)"
```

Update

· The Database Kit doesn't support modifying columns that are made of derived data (i.e. calculated expressions and the results of a join). For example, the following scenario does not work:

You have a module through which you fetch data for a few properties in that entity, including one property through the join. The fetch works fine, but when you update using **saveChanges:**, you get an attention panel titled "Database" with the message "Error occurred during transaction". The workaround is to add another module and fetch the data previously accessed through the join directly. Then, you'll have no problems resaving.

IndexingKit Questions

Q: I need to customize the two methods **source:***aSource* **willWriteRecord:**(unsigned)*record* and **source:***aSource*

didReadRecord:(unsigned)*recor*d from the IXRecordTranscription protocol to do a fast archiving of my custom data. However, I don't understand why *aSource* doesn't respond to the IXRecordManager API. How can I work around this problem?

A: The source inside the IXRecordTranscription protocol methods can either be an IXRecordManager or an IXDataRepository object. In the latter case, the record manager is its delegate. For example, in order to find the record manager, your code should look like this:

```
- source:aSource willWriteRecord:(unsigned)record
{

/* Check whether aSource is an IXRecordManager */
if (![aSource isMemberOf:[IXRecordManager class]])
aSource = [aSource delegate];

/* aSource is now an IXRecordManager */
/* Process your custom data here */
return self;
}
```

Valid for 3.0, 3.1, 3.2

Q: When I archive and unarchive an IXStore object, I am able to write it to a typedstream, but reading it back in gives me a memory protection failure with the following backtrace.

```
Program generated(1): Memory access exception on address 0xe
(protection failure).
0xa025f46 in -[IXStore read:] ()
(gdb) where
#0 0xa025f46 in -[IXStore read:] ()
#1 0x500c9be in InternalReadObject ()
#2 0x500f0f8 in NXReadObject ()
```

Why?

A: The memory smasher occurs in InternalReadObject() (the archiving code) when that method tries to send an **awake** message to the unarchived store, which has been freed. The store was freed because it didn't have transactions enabled and hence was in a partially updated state. To fix this problem, you can, for example, call **commitTransaction** in the **write:** method of your store object to finish all outstanding transactions before archiving. Note that this is only necessary if transactions are not enabled. If transactions are enabled, the store can be archived with incomplete transactions pending, and reading it back drops the uncommitted changes. See the code snippet below:

```
/* Make a new storage object with a brand new IXStore */
- init
{
[super init];
storage = [[IXStore alloc] init];
return self;
}

/* Archiving myself */
```

```
- read:(NXTypedStream *)stream
{
[super read:stream];
storage = NXReadObject(stream);
return self;
}

- write:(NXTypedStream *)stream
{
[super write:stream];
/* A convenient place to finish outstanding
transactions. Not needed if transactions are
enabled.
*/
[storage commitTransaction];
NXWriteObject(stream, storage);
return self;
}
```

Please note that this program crasher has been fixed in Release 3.2, and an exception error is raised instead. However, you still need to follow the above guideline to properly archive an IXStore object.

Valid for 3.1, 3.2

MusicKit Questions

Q: As I understand it, the MIDI timer and I/O is handled with the *msg_receive* call, which is a kind of polling that happens whenever the application has time to poll. But if the application is busy with other things, might not the polling interval become too great or too variable, which could have a musically unacceptable effect?

A: It's true that your application must go into a **msg_receive** to receive MIDI. However, it's possible to structure your application so that there is a separate Mach thread that does nothing or little else than service this **msg_receive**. This should provide the response time you need. For example, if you use the MusicKit (see ../NEXTSTEP_Developer/Other_Kits/music_software), there is a feature that allows the MusicKit performance (and, hence, the MIDI **msg_receive**) to run in a separate thread from the graphics event loop. (This feature is also useful for non-MIDI performances, such as those using DSP synthesis.) Alternatively, if you don't use the MusicKit, you can fork your own thread to handle the MIDI asynchronously to the event loop.

Running the Music Kit in a separate thread makes it unlikely that graphics will prevent you from receiving your MIDI in a timely fashion. However, the MusicKit scheduler (just like the AppKit event loop) is non-preemptive<there's no absolute limit to how much can be done before going back to the **msg_receive**. Therefore, if you write your own Performer, Instrument, or NoteFilter subclass, make it as efficient as possible, because you won't receive MIDI until you exit your code. In principle, the way to get the fastest MIDI response is to have your own separate thread loop processing the MIDI, without using the MusicKit. However, if that thread does much processing other than receiving MIDI, using the MusicKit would probably be just as efficient (and easier to program). The important

thing is to get back to the **msg_receive** as quickly as possible, whether in the MusicKit, the AppKit, or your own thread.

Valid for 1.0, 2.0, 3.0

Q: What music software is available for NeXT Computers?

A: There is a variety of third party music software available. See the Software and Peripherals Catalog for more details on these programs. You can obtain the catalog by calling 800-848-NeXT in the U.S.

The Music Kit' is an extensive development tool for programmers and is available in the CCRMA (Stanford's Center for Computer Research in Music and Acoustics) Music and DSP tools distribution. Send mail to musickit@ccrma.stanford.edu for more information. There are some music demos that can be used by non-programmers, such as ScorePlayer and Ensemble. Ensemble combines MIDI in and out with DSP synthesis, soundfile playback, real-time algorithmic composition, interactive note processing, and more.

In the /NextDeveloper/Examples directory, the SoundAndMusic subdirectory contains programs that are runnable by anyone who knows enough Unix to change directories and compile in a shell window.

Some public-domain software is available on the Internet archive servers. Z-quencer is a simple MIDI sequencer with the music displayed in piano-roll style (rather than as music notation). Looching is a program that plays continuous background music on the DSP. Programmers at NeXT created the Lisp Scorefile Package, a Lisp front end for generating Music Kit scorefiles, and RecordApp, a program for sound recording.

Also available for programmers are some environments for software (non-real-time) sound synthesis and soundfile processing, mostly ported from other Unix platforms. Some also do real-time DSP synthesis. Generally these are available with source for a nominal fee or free of charge. CSound was created at M.I.T. and was given a NeXT front end by Pete Yadlowsky (pmy@virginia.edu). F. Richard Moore at U. C. San Diego (frm@sdcarl.ucsd.edu) has ported cmusic, a software synthesis language, and pvoc, a phase vocoder (for sophisticated analysis and resynthesis of recorded sound). Paul Lansky at Princeton ported cmix and rtmix, programs for soundfile processing and mixing. John Rahn at the University of Washington (jrahn@blake.washington.edu) has a Lisp kernel for music composition. Mara Helmuth (mara@woof.columbia.edu) wrote Patchmix, a graphical unit generator patch program that helps you construct synthesis instruments and that writes out cmix code.

At Stanford University, Heinrich Taube has created Common Music, a compositional environment based on the Common Lisp Object System; it creates scorefiles, soundfiles, and DSP synthesis using the Music Kit. Bill Schottstaedt has developed Common Lisp Music, a Lisp-based software synthesis language that uses the DSP for acceleration rather than real-time synthesis. Perry Cook has written SPASM, an interactive vocal synthesis application, ResonatorLab, a real-time digital filter application, and miscellaneous other tools that can be used by non-programmers. Glen Diener is developing a music notation program. Bill Schottstaedt has made available another music notation package, called cmn,

in which editing is done from Lisp rather than graphically. The Stanford materials are available by anonymous ftp to ccrma.stanford.edu.

At Northwestern University, Bill Parod (bill_parod@nwu.edu) has created Just, a NeXT Music Kit application for exploring tuning systems and for retuning scorefiles.

There is an extension to TeX for music notation called MuTeX. We are told this works with the NeXT version of TeX, but that it doesn't include 92dpi screen fonts, so you have to print the scores on your printer to see the notation. Presumably someone could use TeX's companion program METAFONT, also bundled on NeXT's 2.0 Extended software release, to create a 92dpi screen font from the provided MuTeX fonts.

Note that there are non-NEXTSTEP programs available for other platforms that might run on NeXT computers under SoftPC or X. For example, SCORE is a powerful music notation program for the IBM PC, and there are some public-domain sound tools that run under X windows.

There is an email-based music interest group that occasionally has announcements of new music-related software for the NeXT. To subscribe, send email to next-music-request@wri.com.

Motorola: Hardware Q & A

Disclaimer

This document pertains to the Motorola 68k-based hardware systems sold by NeXT Computer. Apple Computer no longer offers hardware support for these computers. This information is provided only as a convenience to our customers who are still using this hardware. Questions in this Q&A document that refer to the NeXTSTEP operating system may not apply to version 3.3 or to any other specific version of NeXTSTEP.
This article has been archived and is no longer updated by Apple.

NeXTdimension Questions

Q: What is the programming environment for NeXTdimension?? Can a user program the i860 directly or does he/she have to use Display PostScript or NEXTSTEP? Can I program the NeXTdimension board directly?

A: No, it is not possible to write code (in C or Assembly language) that will run on the i860 processor on NeXTdimension.

The purpose of the processors on the NeXTdimension is to manage the 32-bit MegaPixel display. This consists of assisting in the rendering and manipulation of tremendous amounts of data on the screen, managing the backing store, virtual memory, and video data, and all the rest. In order to do this in an efficient and timely manner, we felt that providing a lower level API (like programming the board directly in Assembler) would sacrifice these goals.

In providing an Assembly/C language interface, we would have to also do some sort of timesharing, in order to ensure that the the display system would have control of the NeXTdimension when it needed it. This is not a simple task.

In addition to this, providing the Assembly/C language interface leaves third party developers vulnerable to future changes in the display system. By using the AppKit and Display PostScript, applications are cushioned from future changes. Rather than having large numbers of graphics customers with gross incompatibilities whenever we revise our display architecture, instead we have customers whose applications run across our entire line, albeit faster on some machines than others.

What you do get in the NeXTdimension system is very fast image manipulations. When you use NXImage, or do image operations in PostScript, these operations are speeded up, without any changes in your code. In addition, the processors on NeXTdimension makes it possible to manipulate 32-bit color images and video with excellent performance.

Q: What files are required for a NeXTdimension board to function properly?

A: The NeXTdimension-related files on Release 2.1 and later (NeXTdimension systems only) are as follows:

ND PostScript Driver:
In the directory /usr/lib/NextStep/Displays/NeXTdimension.psdvr:

reloc dynaloads into WindowServer
ND_MachDriver_reloc loaded into Mach

NDserver loads i860 code and provides I/O support

NOTE: The size of the virtual memory space on the i860 is directly related to the VSIZE that ps reports for the NDserver task. This task shows up in the output from **ps aux** as:

root 149 0.0 3.4 28.3M 280K ? S 40:47 (NextDimension) -NDSlot 2

CPU use by this task directly reflects I/O activity, including paging, by the i860.

Video Support:
/NextDeveloper/Headers/appkit/NXLiveVideoView.h include file for video view
/usr/lib/NextStep/GraphicsPackages/video_reloc dynaloads into WindowServer
/usr/shlib/libMedia_s.A.shlib shlib image
/usr/lib/libMedia_s.a shlib archive

(Prior to Release 3 the video library is libvideo_s instead of libMedia_s.)

Demos & Examples:
NeXTtv video/grab Demo
ScreenScape video out Demo
VideoApp generic video Example

Q: I've purchased a NeXTdimension system and wish to expand the memory. What performance advantages can I expect to gain from adding memory to the NeXTdimension board as opposed to the CPU board? Is there a mini-Mach running on the i860? Can the i860 swap to disk? Can I memory-map the memory on the ND board?

A: The DRAM on the NeXTdimension is used for displaying all windows which appear on the NeXTdimension monitor. The NeXTdimension board is driven by a Mach loadable device driver (which loads into the Mach kernel on the host) and a NeXTdimension screen driver, part of which loads into the WindowServer, and another part which loads into the i860. This i860 software consists of a mini Mach-like kernel, specially designed to support low-level PostScript drawing, 3D rendering, and virtual memory for window backing stores. It is NOT possible to program the i860 directly.

Neither the DRAM nor the VRAM on the NeXTdimension can be memory mapped by the application. When it becomes necessary, the i860 pages to disk via the host 68040<it does not write directly to disk itself.

Whether you increase memory on the 68040 or the NeXTdimension depends upon how you plan to use the system. In general we recommend that you keep them fairly balanced. If you are going to be keeping lots of windows on the ND system then we suggest that you keep the memory on the i860 somewhat ahead. The less paging you do the better. You cannot extend the VRAM [video ram] on the NeXTdimension.

Q: Why does NeXTSTEP run so slowly on my NeXTdimension?

A: The key to NeXTdimension configurations is simple<don't set the monochrome MegaPixel Display as the default screen if you configure the NeXTdimension system with

both monochrome and color displays. This configuration causes the NeXTdimension to run very slowly.

The NeXTdimension can be run either with just a color display, or with both monochrome and color displays simultaneously. For best performance when running with both displays, the color display should be set as the default screen. Make sure that your customers don't configure their systems to default to the monochrome display. This configuration works, but works very slowly.

For example, zooming to 200 percent in Scene while looking at a large TIFF file takes 130 seconds with the slow configuration. With any other NeXTdimension configuration, it takes only about 20 seconds.

How does this happen? With a new NeXTdimension system or upgrade to an existing NeXTcube, the system will power up and, by default, use only the color display. To configure a system with multiple displays, the user must run the Preferences application and use the multiple screens preference item to enable the monochrome screen.

The only way to get into the slow configuration is to drag the loginwindow icon over the monochrome screen to set it as the zero screen. Customers who may have already set this configuration can set the zero screen back to the color screen by dragging the loginwindow icon over to the color screen.

NeXT Printer Questions

Q: Where can I find replacement cmyk cartridges for my NeXT Color Printer?

A: The NeXT Color Printer uses the same engine as the Canon BJ 800/820 printers. Cartridges compatible with those printers can also be used with the NeXT printer.

Q: Can the cable for the NeXT Laser Printer be extended somehow?

A: No. There will be too much signal skew.

Q: What is the maximum weight of paper you can use in the NeXT Printer? What is the maximum size and number of pages you can use in the NeXT Printer?

A: Different countries use different paper measurement schemes.

In the United States, paper weight is traditionally measured in "pounds per square foot." In Europe it is measured in grammes per square meter (gsm).

· **Maximum Paper Size/Weight**
Cassette feed
60-80 gsm paper (Grammes per square meter or g/m2)
or
34 pound paper

Manual feed
Plain paper from 100mm x 175mm to 216mm x 356mm (60 gsm to 128 gsm).

· **Cassette Capability**
A4/Letter selection (Depth: 16mm - approx 150 sheets of 80 gsm paper)

Q: When shipping a printer, what has to be done to move it safely?

A: Remove the toner cartridge and place it in its own box. If left in the printer, all of the toner could spill out. If you still have the tabs which were removed from the printer when it was first unpacked, place the tabs back into the unit. See the "Setting Up the Printer" Chapter in the Getting Started manual for printer setup information.

Miscellaneous NeXT Computer Questions

Q: How can I change the voice alerts for my printer?

A: In versions prior to Release 3, the voice alerts can be found in the directory /usr/lib/NextPrinter. In Release 3 and later, they are located in /usr/lib/NextPrinter/*language*.lproj, where *language* is the name of language version of the sound you want to change. There are four of them:

manualfeed.snd "Your printer is waiting for paper"
nopaper.snd "Your printer is out of paper"
printeropen.snd "Your printer cover is open"
paperjam.snd "Paper is jammed in your printer"

These are ordinary CODEC-based sound files. One can replace them with one's own recording. (The execute bit need not be on.)

Q: Where can I find replacement cmyk cartridges for my NeXT Color Printer?

A: The NeXT Color Printer uses the same engine as the Canon BJ 800/820 printers. Cartridges compatible with those printers can also be used with the NeXT printer.

Q: When I try to format a floppy disk with my external SCSI floppy drive, it fails and shows an alert panel that says "Cannot initialize disk. See console for errors." In the console I see this message if it is a new unformatted disk:
/usr/etc/disk -i -h localhost -l "UntitledDisk" /dev/rsd1a
Target 5: MEDIA ERROR; block 0H retry 1
Target 5: MEDIA ERROR; block 0H retry 2
Target 5: MEDIA ERROR; block 0H retry 3
Target 5: MEDIA ERROR; block 0H retry 4
Target 5: MEDIA ERROR; block 0H retry 5
Target 5: MEDIA ERROR; block 0H retry 6
Target 5: MEDIA ERROR; block 0H retry 7
Target 5: MEDIA ERROR; block 0H retry 8
Target 5: MEDIA ERROR; block 0H retry 9
sd1 (5,0): sense key:0x3 additional sense code:0x12
SCSI Block in error = 0 (no valid label)

Read of sector 0 failed

If the disk have been formatted and I try to re-initialize the disk, I see this message in the console:
/usr/etc/disk -i -h localhost -l "UntitledDisk" /dev/rsd1a
disk name: PLI SUPER FLOPPY
disk type: removable_rw_scsi
device = /dev/rsd1a block size = 512 capacity = 1 MBytes
Disk Format in progress...
Format Complete
writing disk label
boot block extends beyond front porch

How can I initialize floppy disks?

A: This assumes your external SCSI floppy drive is at sd1.

You must be logged in as, or su'd to root.

(You type the things in bold...)

localhost:18# **sdform /dev/rsd1a**
device = /dev/rsd1a block size = 512 capacity = 1 MBytes

FORMATTING THIS DISK CAUSES ALL DISK DATA TO BE LOST
This will take approximately 5 minutes.

Do you wish to proceed? (Y/anything) Y

Disk Format in progress...
Format Complete
localhost:19# **disk /dev/rsd1a**
disk name: PLI SUPER FLOPPY
disk type: removable_rw_scsi
Disk utility

disk> **label**
label information: print, write? **write**
enter host name: localhost
enter disk label: UntitledDisk
writing disk label
disk> **quit**
localhost:20# **newfs /dev/rsd1a**
setting optimization for space with minfree less than 10
Warning: 12 sector(s) in last cylinder unallocated
/dev/rsd1a: 1392 sectors in 78 cylinders of 2 tracks, 9 sectors
1.4Mb in 5 cyl groups (16 c/g, 0.29Mb/g, 64 i/g)
super-block backups (for fsck -b#) at:
16, 320, 592, 896, 1168,
localhost:21# disk -e /dev/rsd1a
disk name: PLI SUPER FLOPPY
disk type: removable_rw_scsi
localhost:22#

Q: How do I use the serial port as a tty connection?

A: It is pretty much a plug-n-play operation once you have enabled the serial port to be accessed as a tty. You will need a terminal or a communications program which will run on whatever machine you plug into the serial port.

1) As root, edit the file "/etc/ttys" and set a terminal type and baud rate. Be sure to change the "off" to "on". (See "/etc/gettytab" for help in assigning a baud rate. Read the "man" page on "gettytab" and "getty" for more help.) Save the changes and power down.

Default entries in "/etc/ttys" shown below.
ttya "/usr/etc/getty std.9600" unknown off secure
ttyb "/usr/etc/getty std.9600" unknown off secure

2) You will need a null-modem serial cable. This cable switches the transmit and receive wires between the two plugs. Turn both systems off and plug this cable into the serial ports of the two machines.

PC serial port:
_____ Pin Signal
(1 2 3 4 5) --- ------
\\ o o o o o / 2 Receive Data
\\ 6 7 8 9 / 3 Transmit Data
\\ o o o o/
_____/

NeXT serial port:
(see "man zs" located online). Serial ports A and B use 8-pin miniature DIN (MiniDIN-8) connectors. Both ports on a 68040-based NeXT computer are RS-423 compatible; the ports on a 68030-based NeXT computer are RS-422 compatible (though different). The following diagram and table describe the pin configuration of each port: Pin 3 is Transmit Data and pin 5 is Receive Data. (see Appendix B:Cabling in the System Administration Guide located online)

Mini-din signals on 68030 systems:

Pin Signal
1 DTR Data Terminal Ready
2 DCD Data Carrier Detect
3 TXD- Transmit Data Minus
4 GND Signal Ground
5 RXD- Receive Data Minus
6 TXD+ Transmit Data Plus
7 A: RTXC Receive Clock
B: +5v +5 volts
8 RXD+ Receive Data Plus

NOTE: Previous NeXT documentation incorrectly referred to
pin 2 as CTS.

Mini-din signals on 68040 systems:

Pin Signal
1 DTR Data Terminal Ready
2 DCD Data Carrier Detect
3 TXD Transmit Data
4 GND Signal Ground
5 RXD Receive Data
6 RTS Request To Send
7 RTXC Receive Clock
8 CTS Clear To Send

3) Match the settings of your terminal or terminal emulator with those you have selected in "/etc/ttys". The default setting specified in "/etc/gettytab" will accept tty connections with even parity, 7 bits and 1 stop bit ;(E71). PC users will need to specify which com port the terminal program is to use and make sure that the port is enabled in their system's BIOS.

NeXTSTEP Installation Q&A

Disclaimer

This document pertains to the NeXTSTEP operating system (versions 3.2 and previous). Apple Computer no longer provides support for these products. This information is provided only as a convenience to our customers who have not yet upgraded their systems, and may not apply to OPENSTEP, WebObjects, or any other product of Apple Enterprise Software.
This article has been archived and is no longer updated by Apple.

Q: When I try to upgrade from Release 3.1 to 3.2, the Upgrade.app indicates the post-processing script failed. When I checked the upgrade log, I saw the following lines:

There isn't enough space to install all the languages.
ROOT: Undefined variable.

What's going on? How do I get the upgrade to complete? Is the computer now unusable?

Q: The Upgrade.app indicates the post-processing script failed, but then said the upgrade completed successfully. When I restart the computer, it panics with a "Can't mount root" error. What can I do?

A: This happens when there isn't enough free space on the hard disk being upgraded to install the languages packages. The post-processing script fails due to a bug: the environment variable **ROOT** isn't assigned before it's referenced. If you are using an Intel based computer, it is *unusable* if it's restarted; the device driver upgrade isn't complete at this point. If you are using a NeXT computer, English help didn't get installed. However, you *can* complete the upgrade, and thus make the computer usable.

+Intel users who haven't rebooted,
+NeXT computer users before or after rebooting

To complete the upgrade, type the following as the root user in a Terminal window (this assumes you're using the C-Shell as your login shell; if this isn't the case, adapt the following procedure, or start the C-Shell, **/bin/csh**).

Note: This procedure assumes that the 3.2 upgrade CD-ROM is mounted on the directory **/NEXTSTEP_3.2**. If this is not the case, substitute the actual mount point of the 3.2 upgrade CD-ROM for **/NEXTSTEP_3.2** throughout the following procedure.

```
setenv ROOT /NEXTSTEP_3.2
/NEXTSTEP_3.2/Upgrader.app/Default.upgrade/PostProcess / /NEXTSTEP_3.2
```

+Intel users who have rebooted

If you have already rebooted, your computer panics with the "Can't mount root" error. To complete the upgrade at this point, do the following:

1. Insert the 3.1 floppy disk into the floppy disk drive.
2. Start up the computer.
3. At the **boot:** prompt, type:

if you have a SCSI hard drive

```
fd()mach_kernel -s rootdev=sd0a
```

if you have an IDE hard drive
fd()mach_kernel -s rootdev=hd0a
4. At the # prompt, type the following, pressing the Enter key at the end of each line:
mount -o remount /
if you have a SCSI hard drive
mount -o ro /dev/sd1a /NEXTSTEP_3.2
if you have an IDE hard drive
mount -o ro /dev/sd0a /NEXTSTEP_3.2
nmserver -nonet
sh /etc/rc.net -h
portmap
nibindd
csh
setenv ROOT /NEXTSTEP_3.2
/NEXTSTEP_3.2/Upgrader.app/Default.upgrade/PostProcess / /NEXTSTEP_3.2
halt
5. Remove the floppy disk.
6. Restart the computer.

Q: When I try to install NEXTSTEP Release 3.2 for Intel Processors onto my computer, the keyboard locks up, and I am unable to complete the installation.

What's going on? How do I get the installation to complete? Is the computer now unusable?

A: There is a known bug which may lock up your keyboard during installation onto systems which do not have integrated PS/2 mouse support. The problem is in the PS/2 mouse driver, and removing the PS/2 mouse driver from your default configuration will work around the problem.

The following entry will prevent the PS/2 mouse driver from being automatically loaded. By default, NEXTSTEP loads the following drivers during installation and when booting **config=Default**: PS2Keyboard, PS2Mouse, Adaptec1542B, DPT2012, IDE, and Floppy. To remove the PS2Mouse driver from this list, type the following at the **boot:** prompt:

"Boot Drivers"="PS2Keyboard Adaptec1542B DPT2012 IDE Floppy"

While configuring during the installation process, be certain to remove the instance of the PS2Mouse driver which is automatically added by Configure.

Q:I have a two gigabyte or larger SCSI disk drive on which I'm trying to install NEXTSTEP Release 3.2. Everything seems to go fine until the installation program looks for disks to install on; then it can't find my hard disk drive. What's going on?

A:There is a known bug in the NEXTSTEP Release 3.2 installation process such that it will not recognize a hard disk drive larger than two gigabytes. This bug has been fixed in NEXTSTEP Release 3.3. Under 3.3, hard disks larger than two gigabytes will be automatically partitioned into as many two-gigabyte-or-smaller partitions as necessary. For example, a nine-gigabyte hard disk devoted solely to NEXTSTEP would be partitioned into five partitions, each with a size of approximately 9/5 = 1.8 gigabytes.

Q: Are there any peripherals known to be incompatible with NeXTSTEP versions 3.1 or 3.2?

A:There is a known incompatibility with the firmware found in Seagate IDE drives model numbers ST3550a and ST3588A when used with NEXTSTEP 3.1 and 3.2. This error manifests during installation when a sequence of IDE

error messages occur and installation stops. The error "Disk initialization failed" is then reported. A firmware upgrade to fix this problem is available through Seagate. Model ST3550a requires firmware update 9581, and model ST3385a requires firmware update 9588.

Published Date: Feb 18, 2012

NEXTSTEP 3.3 Netware Q&A

Disclaimer

This document pertains to the NeXTSTEP operating system, which is no longer a supported product of Apple Computer. This information is provided only as a convenience to our customers who have not yet upgraded their systems, and may not apply to OPENSTEP, WebObjects, or any other product of Apple Enterprise Software. Some questions in this Q&A document may not apply to version 3.3 or to any given specific version of NeXTSTEP.
This article has been archived and is no longer updated by Apple.

Q: When connected to NetWare I try to transfer files larger than a few bytes in size, the attempt fails and a panel says I am no longer logged into the Netware server. What is going on?

A: There is a bug in NeXTSTEP version 3.3 where if the Netware v3.12 server is using 802.3 frames you will not be able to transfer files over a few bytes in size. The fix is to have the Netware server use a framing type other then 802.3. NeXTSTEP supports frame types: ethernet_ii, ethernet_snap, and ethernet_802.2. There is nothing you will need to change in NeXTSTEP.

Q: After Ugrading from 3.2 to 3.3 I see all the NetWare file servers available. I authenticate on one of the file servers, but can not see any of the directories or files on that server. The only directory listed is "SYS". What is going on?

A: The upgrade failed to update the file "/usr/lib/kern_loader/nuc/nuc_reloc". As "root" you'll need to copy the file off the NEXTSTEP 3.3 CDROM. With your NEXTSTEP 3.3 CDROM mounted, you can do so with the command:

ditto /NEXTSTEP_3.3/usr/lib/kern_loader/nuc/nuc_reloc /usr/lib/kern_loader/nuc

Q: Why does NEXTSTEP not recognize some Netware servers on my network?

A: The simple answer is that not all Netware servers are configured to use the same frame type. Frame type configuration under NEXTSTEP is automatic, so generally there is no need to configure it. When you boot NEXTSTEP, it sends out Nearest Server Query broadcast packets to find the nearest server. It tries twice using Ethernet-II framing, then twice with 802.2 over 802.3, then twice using 802.2 with SNAP headers over 802.3 then twice using raw 802.3. As soon as it gets a response from a server, it stops the search process, and configures itself to use the frame format which triggered the response.

If you want to override the automatic configuration, you can edit
/etc/rc. Find the line which launches /usr/netware/etc/npsd, and
add command-line options to it. Valid options are:

-v << verbose mode >>
-t ss << change timeout on server responses to ss seconds >>
-r nn << try each frame type nn times before giving up >>
-f ethernet_ii << ethernet type II frame type >>
-f ethernet_snap
-f ethernet_802.2
-f ethernet_802.3

For a complete description of npsd under NEXTSTEP 3.3, see the UNIX manual page.

There is no provision for communicating to different servers with different frame types. This means that all servers on your network must be using the same frame type if you want NEXTSTEP to be able to access them all.

TA45929_ComTalk_and_NFS_Compatibility_Update_(TIL07265).pdf

ComTalk and NFS: Compatibility Update

Can I get an update on APT's ComTalk AppleTalk & TCP/IP Routing products and the new NFS software compatibility?

This article has been archived and is no longer updated by Apple.

NFS/Share from Intercon and Wollongong's NFS Client do not work across ComTalk gateways because of lack of support for splitting up and encapsulating larger UDP-type packets over AppleTalk/LocalTalk. These vendors are aware of this problem and are working on a fix. There are no problems supporting TCP-based services, such as Telnet, SMTP, FTP.

Other than this compatibility issue, these products are very fast, and have a comprehensive set of security options.

NEXTSTEP Interface Objects Q&A

Disclaimer

This document pertains to the NeXTSTEP operating system, which is no longer a supported product of Apple Computer. This information is provided only as a convenience to our customers who have not yet upgraded their systems, and may not apply to OPENSTEP, WebObjects, or any other product of Apple Enterprise Software. Some questions in this Q&A document may not apply to version 3.3 or to any given specific version of NeXTSTEP.
This article has been archived and is no longer updated by Apple.

Overview

This document contains development questions relating to windows, views, and other interface objects under NeXTSTEP 3.3 and/or previous versions.

Questions

Q: I would like to convert a point returned in an NXEvent from its base coordinates to a view coordinate system. There are several routines to convert coordinates between views and between the screen and base coordinate systems, but I have not found one to convert a base coordinate to a view's coordinate system. How do I do this?

A: Calling the following method with aView == nil converts the point from the base coordinate system of the window to the view's coordinate system:

```
- convertPoint:(NXPoint *)aPoint fromView:aView;
```

Q: I have a button which, when clicked, removes a View from a Window. However the button that does this is a subview of the View that is removed. This works except I get the following message on the console:

```
Assertion failed: You removed a View from the View hierarchy that had been lockFocus'ed
```

Is this a problem? Can I ignore the message?

A: Typically the action method for a control is called while in the mouseDown for that control. At this point the AppKit has performed a lockFocus on that control (while it is highlighted) and it will not remove the lockFocus until the action method has completed (and the highlight is turned off). For this reason it is not a good idea to be modifying the view hierarchy of any superviews from within the action method of a control. If it is not possible to restructure the code so that the hierarchy is modified outside of the action method, then the next best approach is to perform the action with a slight delay. The code might look like:

```
[self perform:@selector(removeView:) with:sender afterDelay:1 cancelPrevious:YES];
```

Q: How can I make connections in InterfaceBuilder between objects in different nib files, or in the same one loaded multiple times?

A: You can't. You need to make the association in your code. The object that is the nib file's owner should take care of communicating with any other objects (including the owners of other nib files). For example, the file's owner can have methods that return

instance variables referring to any objects from the nib file that you want other objects to be able to talk to. (You must have created outlets in Interface Builder for these objects, in order for the objects to be assigned to instance variables.) The file's owner can also set the delegate of an object it owns to be some external object.

It's conceptually impossible to make the connections in Interface Builder, because there's no way to know which *instance* of an object from one nib file is connected to an instance of some object from another nib file. Each nib file is loaded at a different time during the program execution, and any nib file can get loaded multiple times. Only your code "knows" when the various objects get created<namely, when you call **loadNibSection:owner:**. Remember that nib files are just templates; the objects are unarchived when you load the nib file. When you make connections in InterfaceBuilder, you're really just making the template of these connections. Only when the nib file is loaded do the objects and their interconnections get instantiated, so to speak. If the other nib file hasn't been loaded yet, you can't connect to its objects, since they don't exist in your program yet. That's why connections are limited to nib files. It's also one reason every nib file must have an owner: so that objects from that nib file can communicate with other objects in your program.

The same logic applies to loading the same nib file multiple times. A typical use of loading the same nib file multiple times is in applications that have the notion of a document. The document is described by a nib file that gets loaded each time you want a new document (usually when the user clicks on the "New" menu). There should generally be a new instance of the owner of the nib file for each time you want to load the same nib file. The only way to communicate between the objects in different documents is through their owners.

One example of multiply loaded nib files is /NextDeveloper/Examples/SoundAndMusic/SoundKit/SoundEditor. In this application, SoundController is the main object that loads in the application's main nib file. It also is responsible for creating SoundDocuments, each of which loads in its own nib data. In other words, a new instance of the SoundDocument class is the file's owner for each "instance" of SoundDocument.nib<or more precisely, for the objects collectively unarchived each time

```
[NXApp loadNibSection:SoundDocument.nib owner:self];
```

is called in SoundDocument's **init** method. Although it wasn't necessary, there could have been methods in SoundDocument to return the objects "inside" each SoundDocument's nib file. For example, SoundDocument could have implemented a method called **-soundView** that returned the variable **mySoundView**, which is an InterfaceBuilder outlet. This way any other objects could have talked to the SoundView, by messaging SoundController to get the current document (with the **document** method), and then messaging the current document to get its SoundView (with the **soundView** method).

Q: How do I programmatically create a window 80 characters wide for any given font?

A: The following code snippet works for a fixed width font such as Ohlfs or Courier. A non-fixed width font can only be approximated by choosing either an "average-width"

character, or the widest character in the font.

```
#import <math.h>
#import <appkit/Window.h>
#import <appkit/Font.h>

float maxcharwidth, screenwidth;
id screenFont, myWindow;
NXCoord leftMargin, rightMargin, topMargin, bottomMargin;
NXRect aRect;

[myText getMarginLeft: &leftMargin
right: &rightMargin
top: &topMargin
bottom: &bottomMargin];
screenFont = [myFont screenFont];

maxcharwidth = MAX([myFont getWidthOf: "0"],
[screenFont getWidthOf: "0"]);
screenwidth = ceil(maxcharwidth * 80.0) + leftMargin + rightMargin +1;

/* Now use that width when creating the window */
NXSetRect(&aRect, 0.0, 0.0, screenwidth, height);
#ifdef 1.0
myWindow = [Window newContent: &aRect
style: NX_TITLEDSTYLE
backing: NX_BUFFERED
buttonMask: NX_MINIATURIZEBUTTONMASK
defer: NO];
#else /* 2.0 or 3.0 */
myWindow = [[Window alloc] initContent: &aRect
style: NX_TITLEDSTYLE
backing: NX_BUFFERED
buttonMask: NX_MINIATURIZEBUTTONMASK
defer: NO];
#endif
```

Note that the ifdef for 1.0 is for illustration purposes only and is NOT defined in any NEXTSTEP include file.

The key is to get the width of any character (since all have the same width) of both the screen font and the printer font. Take the maximum width and do a ceil of the calculation, since the printer width may be fractional.

Note that a fudge factor of +1 is added to the calculation. This is a known bug.

Note also that this window does not contain a vertical scrollbar. If it did, the width of the scrollbar would need to be accounted for.

Q: How can my program tell whether it is running on a system with a color screen?

A: The PostScript graphics model allows you to do all your rendering in 24 bit color, and have the WindowServer display it in the best way possible (dithering down to 2 bits, if necessary). If there are situations in which you need to use the "inquire and adapt" approach, the AppKit provides you with a method in the Application class called **colorScreen** that returns the most colorful screen available to your application. By

examining this data structure, you can determine how deep your color screen is. Below is a code fragment that does this:

```
#import <appkit/Application.h>
#import <appkit/screens.h>
...
{
const NXScreen *deepestScreen;

deepestScreen=[NXApp colorScreen];

switch ( deepestScreen->depth ) {

case NX_TwelveBitRGBDepth :
/* Twelve Bit Color */
break;

case NX_TwentyFourBitRGBDepth :
/* True Color */
break;

case NX_TwoBitGrayDepth :
default :
/* Greyscale */
break;

}
}
```

Q: How can I tell whether a View can display color or not?

A: The previous question does not answer which kinds of rendering commands you should be sending for a given View. There are two headed systems, and other circumstances where the window you are drawing in is not based on the value of **colorScreen**. The most common thing you want to do is different rendering based on whether this View can display color or not. One way to do this is to use the **shouldDrawColor** method of View. Do the following in your drawSelf:: method for the View:

```
- drawSelf:(NXRect *)rects :(int)count
{
if ([self shouldDrawColor]) {
... color-specific drawing ...
} else {
...
}
...
}
```

If you need to know the actual depth of a given window, use the **depthLimit** method of Window. Here's some code for that:

```
NXWindowDepthLimit depth;
if ((depth = [myWindow depthLimit]) == NX_DefaultDepth) {
depth = [Window defaultDepthLimit];
}
```

Q: How do I display a new window I created programmatically?

A: If you allocate a window and initialize it with the **init** method, that window, by default, has display disabled. When display is disabled, the window appears on-screen without a title and its contentView is white. You must send it a **display** message to get things going (i.e., so that it draws itself properly). Simply sending it **orderFront**: is not sufficient.

If your window is allocated and initialized with the **initContent:style:backing:buttonMask:defer:** method, display is disabled only if the defer flag is set to NO. If it's YES, the window looks fine when it gets the **orderFront**: message.

Q: How do I make a window resize from a corner other than the upper right?

Q: I have a view that I want to resize. However, what I really want is for the window to be resized such that my view becomes the given size using the autosizing attributes that I have set in my window. How do I do that?

A: The following window method, sizeWindow:byCorner:, resizes a window to the given size by moving the given corner. The view method below it, sizeTo::byWindowCorner:, resizes a view by growing its window such that the view becomes the given size with respect to its autosizing settings. The two methods are implemented as categories to Window and View respectively.

```
// Format is 80 columns with 4 space tabs.
@interface Window(Sizing)
- sizeWindow:(NXCoord)width :(NXCoord)height byCorner:(int)corner
@end

@implementation Window(Sizing)

#define CORNER_UPPER_LEFT 0
#define CORNER_LOWER_LEFT 1
#define CORNER_UPPER_RIGHT 2
#define CORNER_LOWER_RIGHT 3

// Keep 'a' between x and y
#define CLAMP(a,x,y) (MAX((x), MIN((y), (a))))

/*****************************************************************************
This Method resizes the receiving window as if it was dragged with the given corner. This method is useful when you want the window to resize by a corner other that the default upper right.
*****************************************************************************/
- sizeWindow:(NXCoord)width :(NXCoord)height byCorner:(int)corner
{
NXRect newFrame;
NXSize minSize, maxSize;

// Clamp width and height to their respective minimum and maximum values
[self getMinSize:&minSize]; [self getMaxSize:&maxSize];
width = CLAMP(width, minSize.width, maxSize.width);
height = CLAMP(height, minSize.height, maxSize.height);

// Set newFrame from the old frame and the new sizes
NXSetRect(&newFrame, NX_X(&frame), NX_Y(&frame), width, height);

// Move the respective corner by the amount of growth and set newFrame
switch(corner) {
case CORNER_UPPER_LEFT:
NX_X(&newFrame) -= width - NX_WIDTH(&frame);
```

```
break;
case CORNER_LOWER_LEFT:
NX_X(&newFrame) -= width - NX_WIDTH(&frame);
NX_Y(&newFrame) -= height - NX_HEIGHT(&frame);
break;
case CORNER_UPPER_RIGHT:
break;
case CORNER_LOWER_RIGHT:
NX_Y(&newFrame) -= height - NX_HEIGHT(&frame);
break;
}
[self placeWindowAndDisplay:&newFrame];
return self;
}
@end

@interface View(Sizing)
- sizeTo:(NXCoord)width :(NXCoord)height byWindowCorner:(int)corner;
@end

@implementation View(Sizing)

/*****************************************************************************
This Method resizes the receiving view to the given width and height by resizing the window by the appropriate amount with respect to autosizing. This method is useful for those occasions when you know what size a view should be, but don't know how big to make the window to hold it. If you ask for a new width, it assumes the view is width sizable. The same goes for height. If the hierarchy contains a ClipView (ie, in a ScrollView) it assumes that you want the ClipView's subview to be fully exposed. The window size will not exceed the set maximum.
*****************************************************************************/
- sizeTo:(NXCoord)width :(NXCoord)height byWindowCorner:(int)corner
{
int autosizing = [self autosizing];
float widthGrowth = width - NX_WIDTH(&bounds);
float heightGrowth = height - NX_HEIGHT(&bounds);
float stretchingWidth = NX_WIDTH(&bounds);
float stretchingHeight = NX_HEIGHT(&bounds);
float newSuperWidth, newSuperHeight;
NXRect superFrame;

// If we are a contentView we simply need to grow window by our growth
if(self==[window contentView]) {
[window getFrame:&superFrame];
[window sizeWindow:NX_WIDTH(&superFrame) + widthGrowth
:NX_HEIGHT(&superFrame) + heightGrowth byCorner:corner];
}
else {
[superview getFrame:&superFrame];

// Add margins to stretching lengths if they have been turned on in IB
if(autosizing & NX_MINXMARGINSIZABLE) stretchingWidth += NX_X(&frame);
if(autosizing & NX_MAXXMARGINSIZABLE)
stretchingWidth += NX_WIDTH(&superFrame) - NX_MAXX(&frame);
if(autosizing & NX_MINYMARGINSIZABLE)
stretchingHeight += NX_Y(&frame);
if(autosizing & NX_MAXYMARGINSIZABLE)
stretchingHeight += NX_HEIGHT(&superFrame) - NX_MAXY(&frame);

// Add growth times a ratio of stetching length::view length to Super
newSuperWidth = NX_WIDTH(&superFrame) +
widthGrowth*stretchingWidth/NX_WIDTH(&bounds);
newSuperHeight = NX_HEIGHT(&superFrame) +
heightGrowth*stretchingHeight/NX_HEIGHT(&bounds);

// Resize the Superview
[superview sizeTo:newSuperWidth :newSuperHeight
```

```
byWindowCorner:corner];

// If we are a ClipView, bring the docview up to size
if([self isKindOf:[ClipView class]])
[[(ClipView *)self docView] sizeTo:width :height];
}
return self;
}
```

Q: How can I make a non-rectangular Window?

A: You cannot at present make a non-rectangular Window. We hear the request. Tell us how important is this ability compared with your other needs. The WhatADrag example on the 2.0 release (/NextDeveloper/Examples/WhatADrag) shows you how to create windows with transparency for dragging arbitrary shapes on the screen between windows. This does not produce true transparent windows, but it accomplishes most of what developers need transparent windows for.

Q: How can I make a non-rectangular View?

A: You can clip a View to a non-rectangular shape by creating a subclass of View, and overriding the following View method to establish your own clipping path.

```
- clipToFrame:(const NXRect *) frameRect
/*
* TYPE: Focusing and displaying; Clips to frame during focusing
*
* This method is provided to allow for your View to do arbitrary clipping
* during focusing. This method is called from within the focusing
* machinery if clipping is required. The default implementation just
* calls PSrectclip with the values in frameRect. You must use frameRect
* rather than just looking at your View's frame instance variable,
* because due to focusing, the origins may not be the same.
*/
{
PSrectclip(NX_X(frameRect), NX_Y(frameRect),
NX_WIDTH(frameRect), NX_HEIGHT(frameRect));
return self;
}
```

In addition, the 3.0 documentation on clipToFrame: contains an example of clipping the View to a circular region.

Q: I am using the Windows submenu. For each new window document that I create in my application, a new menu cell is added to the submenu with the window's title and a small X at the left-most edge of the menu cell. How do I programmatically control this X to make it broken when the document associated with the menu cell has been changed?

A: The window method setDocEdited: (BOOL)flag is responsible for displaying the broken X when it is set to YES. This method controls both the X in the menu cell, and the X on the upper right corner of the window. It has to be reset to NO **before saving the document**, so that the X reappears as non-broken. See the code snippet below:

/* In the case of a text object for example,this text delegate method is responsible for notifying that the document has changed. Please note that ruler and font changes as well as changes caused by spell checking the Text are not reflected by this text delegate method.
*/

```
- textDidChange: sender
{
[currentDocWindow setDocEdited:YES];
return self;
}
```

/* Remember to reset setDocEdited to NO **before saving** your file, so that the X shows as a regular X **when reading the file back in.**
*/

```
- saveFilename:(const char *)filename
{
[currentDocWindow setDocEdited:NO];

/* To generate a textDidChange message */
[currentDocWindow makeFirstResponder:currentDocWindow];
.....
return self;
}
```

/* After setting setDocEdited to YES, the state of isDocEdited is YES. You can query this state and, if appropriate, display an alert panel before the window closes. Note the use of NXStringTable here for ease of localization. Please refer to our user interface guidelines and release notes for more details.

*/

```
#define SAVE NX_ALERTDEFAULT
#define CLOSE NX_ALERTALTERNATE
#define CANCEL NX_ALERTOTHER

- windowWillClose:sender
{
int result;

if ([currentDocWindow isDocEdited]) {
if (!stringTable)
stringTable = [[NXApp delegate] stringTable];
result = NXRunAlertPanel([NXApp appName],
[stringTable valueForStringKey:
"The document %s has unsaved changes.\\nClose anyway?"],
[stringTable valueForStringKey:"Save"],
[stringTable valueForStringKey:"Close"],
[stringTable valueForStringKey:"Cancel"],
[currentDocWindow title]);
switch(result) {
case SAVE:
...
break;
case CLOSE:
break;
case CANCEL:
return nil;
}
```

```
}

.....

return self;
}
```

Q: How do I disable/enable menu cells?

A: The method setUpdateAction:(SEL)aSelector forMenu:aMenu is responsible for the menu cell update, where aSelector is your own update method, and aMenu the menu you want to update. This method has to be called inside appDidInit: because NXApp is responsible for the update. Doing so makes your program more efficient, since it needs to be done only once.

Q: Should I use the application method setAutoupdate:(BOOL)flag or the menu update method for updating the menu items? What are the trade-offs?

A: The application method setAutoupdate:YES causes the menus to stay up to date all the time (i.e., it only updates them when they are on-screen). Calling update directly every time something changes might be a lot of extra work for nothing. However, if things rarely change in the menu, it might be worth not incurring the window list traversal setAutoupdate: causes.

Example (adapted from /NextDeveloper/Examples/Draw)

```
static void initMenu(id menu)
/* A private C function:
* Sets the updateAction for every menu item which sends to the
* First Responder (i.e. their target is nil).
* Returns the active menu if is found in this menu.
*/
{
int count;
id matrix, cell;
id matrixTarget, cellTarget;

matrix = [menu itemList];
matrixTarget = [matrix target];

count = [matrix cellCount];
while (count--) {
cell = [matrix cellAt:count :0];
cellTarget = [cell target];
if (!matrixTarget && !cellTarget) {
[cell setUpdateAction:@selector(menuItemUpdate:) forMenu:menu];
} else if ([cell hasSubmenu]) {
initMenu(cellTarget);
}
}
}

/* Initializes the updateAction method for the menu cells.
setAutoupdate:YES means that updateWindows will be called
after every event is processed (to keep the menu items up to date).
*/
- appDidInit:sender
```

```
{
.....
initMenu([NXApp mainMenu]);
[NXApp setAutoupdate:YES];
return self;
}

#define TOGGLE 4 /* Some integer cell tag value */

- (BOOL)menuItemUpdate:menuCell
/* Here goes your own code for menu cell update. This is only a simple example
which toggles the state of the selected cell. The return value YES means
that the menu will be updated.
*/
{

BOOL cellState;

switch ([menuCell tag])
{
case TOGGLE: /* toggle menu cell state */
cellState = [menuCell isEnabled];
[menuCell setEnabled:!cellState];
return YES;
default:
break;
}

return NO;
}
```

Q: How do I find the id of a menu?

A: To obtain the menu id of the main menu use this:

```
[NXApp mainMenu]
```

There is no direct way to find the id of other menus unless you know the menu cell which corresponds to the menu in question. Then you can use the ActionCell method target which returns the target of the cell (i.e., its menu id). This method can be used to find any menu id. It is especially useful for finding the id of a submenu.

Example:

```
myMenuId = [myMenuCell target];
```

Q: How can I remove a menu cell from a menu? I can disable, enable, add, sizeToFit, update, and free, but I cannot get the actual cell to disappear from the submenu.

A: You need to remove the cell from the matrix maintained by the menu, and then have the menu resize to fit its new cells. Here is a code snippet:

```
- removeMenuCell:(int)cellNum from:theMenu
{
id matrix;

[theMenu disableFlushWindow];
matrix = [theMenu itemList];
```

```
[matrix removeRowAt:cellNum andFree:YES]; // remove cell
[theMenu sizeToFit]; // adjust menu to new size
[[theMenu reenableFlushWindow] flushWindow];
return self;
}
```

You can disable window flushing before removing the cell to avoid screen flicker, but be sure to reenable it once you're done. The above method is used if you know the number of the cell you want to remove. If you only have the menu cell's title, you can do this:

```
- removeMenuCellName:(const char*)cellTitle from:theMenu
{
int i, count;
id matrix, cells;
id cell;
const char* title;

[theMenu disableFlushWindow];
matrix = [theMenu itemList];
cells = [matrix cellList]; // get the List of cells
count = [cells count];
for(i = 0; i < count; i++)
{
cell = [cells objectAt:i];
title = [cell title];
if(title && !strcmp(title, cellTitle))
{ // compare to find correct title
[matrix removeRowAt:i andFree:YES];
break;
}
}
[theMenu sizeToFit]; // resize menu
[[theMenu reenableFlushWindow] flushWindow];
return self;
}
```

Q: Why does my View lose its TIFF image after I make a call to **setFlipped**? Here is what I did, and the results I got.

Description:

1. Create a viewScroller
2. Create an imageView
3. [viewScroller setDocView: imageView];
4. [imageView setFlipped:YES];
5. load tiff file into imageView
6. [imageView display];

Results:

1. Without the setFlipped: call, my TIFF image shows up fine, with the scrollers sized respective to the imageView.
2. With the setFlipped: call, my TIFF image DOES NOT show up, BUT the scrollers are sized respective to the imageView AND the y-axis scrollbar shows at the top (like it should be).

A: If you composite your TIFF image at the point (0,0), after flipping the view, you won't see anything because the image is in fact now off-screen, i.e. showing at the top left corner (imagine the image height going beyond the y axis<growing upward). However, if you composite at the point (0, height of view rectangle), the image is shown at the lower left corner. Now, if you composite at the point (0, height of the image), the image is shown as hanging from the top left corner.

Q: I created a pop-up list by dragging it from the InterfaceBuilder palette into a window, but it doesn't seem to be freed when the window is freed.

A: This is a bug. Freeing a window *does* free all of its views, but the pop-up list is not a member of the view hierarchy! It's attached as the target of a Button. There are two situations in which this bug can bite an unwary programmer:

1) An application creates multiple document windows by loading a nib section multiple times. In the nib section, there's a window containing a pop-up list. The application leaks a pop-up list instance and a DPS window each time a document is closed. Furthermore, MallocDebug's "Leaks" button won't find the missing nodes because a pop-up list is a window, and there are pointers to the missing pop-up lists in [NXApp windowList].

2) Same situation as in (1), except that each time, the nib section is loaded into a unique zone, and the zones are destroyed when the documents are closed. Destroying the zone gets rid of all the garbage, but now there are bad pointers in [NXApp windowList]. Some time later, the application crashes in code that you didn't write, referencing objects that you don't know about, leaving you very confused.

The solution is to free the pop-up list when you free the window. When setting up the nib file, make an outlet to the Button. In your code, use the outlet to ask the Button for its target before you free the window. The target is the pop-up list, which you then free explicitly.

Q: If I have a window delegate, which method should I use to close the window, the **close:** method or the **performClose:** method?

A: The **performClose:** method should be used instead of **close:** because it sends a **windowWillClose:** to its delegate, while the **close:** method doesn't. See the documentation in the reference manual about the window class for more information about these two methods.

Q: How do I set the current selection on a Popup?

A: In Release 2 and later, InterfaceBuilder has an object on the palette that presents a popup menu of choices. This is actually a button (when you ask InterfaceBuilder for the class of this object, sure enough, it's a button). It's a special button whose target is a PopUpList and action causes the popup menu to be displayed. There is no special message for setting the current selection of this popup, all you do is set the title to be the choice you want to set your popup to, as you would for an ordinary Button. So, if you have an outlet for a popup called "popUpButton" you can do this:

```
[popUpButton setTitle:"Item2"];
```

To get the number of the item currently selected, you have to send the indexOfItem: message to the PopUpList (which is the target of the popup Button). So, with the example above, you would use:

```
num=[[popUpButton target] indexOfItem:[popUpButton title]];
```

Q: In my application when my window becomes the key window or the main window, sometimes it doesn't display itself. What's going on?

A: There is a bug where **display** sometimes is disabled in a Window when the window becomes key and/or main. The result is that a window (or its delegate) tries to do some drawing in its **becomeKeyWindow** or **becomeMainWindow** (or **windowDidBecomeKey:** or **windowDidBecomeMain:**) method, and the drawing doesn't happen because some drawer observes that display is disabled.

Here's a workaround. You can do this little dance in either your delegate method or your override of Window's **becomeKeyWindow** or **windowDidBecomeMain**.

```
- windowDidBecomeMain:win
{
BOOL displayWasDisabledForActivation = [NXApp _isInvalid] &&
![win isDisplayEnabled];

if (displayWasDisabledForActivation)
[win reenableDisplay];

/* whatever you do now... */

if (displayWasDisabledForActivation)
[win disableDisplay];
return self;
}
```

The _isInvalid method is a private method, and as such is undocumented. Calling this ensures that you are in the case where this bug bites. We thought this might be prudent in case there was a different time when you really would like display to be disabled.

Valid for 2.0, 3.0

Q: I have a button which, when clicked, removes a View from a Window. However the button that does this is a subview of the View that is removed. This works except I get the following message on the console:

```
Assertion failed: You removed a View from the View hierarchy that had been lockFocus'ed
```

Is this a problem? Can I ignore the message?

A: Typically the action method for a control is called while in the mouseDown for that control. At this point the AppKit has performed a lockFocus on that control (while it is highlighted) and it will not remove the lockFocus until the action method has completed (and the highlight is turned off). For this reason it is not a good idea to be modifying the

view hierarchy of any superviews from within the action method of a control. If it is not possible to restructure the code so that the hierarchy is modified outside of the action method, then the next best approach is to perform the action with a slight delay. The code might look like:

```
[self perform:@selector(removeView:) with:sender afterDelay:1 cancelPrevious:YES];
```

There is also an example of this method in the DrawApp class of the Draw example.

Valid for 1.0, 2.0, 3.0

Q: I am trying to draw something to my view and am getting the message:

```
Assertion failed: No REAL window during lockFocus on a view
```

I've checked and the window instance variable of the view is non-nil. Why am I getting this message?

A: A REAL window is a PostScript window. Your check for a non-nil window assures that you have a AppKit-side window, but it doesn't check to make sure there is an associated PostScript window. When you grab a window in InterfaceBuilder, it is deferred by default. When a window is deferred the associated PostScript window won't be created until you actually bring that window on screen. You cannot draw to a window which doesn't yet have a PostScript window. You can change the deferred status using the ªDeferredº switch button on the InterfaceBuilder Window inspector or with the proper argument to the Window method (**initContent:style:backing:buttonMask:defer:**). If you're ever in doubt about a view's status, you can use the **canDraw** method which returns a boolean which indicates whether you are able to draw to that view.

Valid for 1.0, 2.0, 3.0

Q. The CompositeLab example in /NextDeveloper/Examples/AppKit sometimes hangs when I drag in non-standard image types for which filters need to be run. Typically it wakes up after a minute or so without having accepted the image; however, if I drag the same image in again, it accepts it without a problem.

A. During a drag session, an application should not make calls to Workspace or call methods and functions that would require contacting Workspace. Launching filter services, applications, obtaining icons for files, sliding images, and methods in the Workspace protocol fall in this category. Making such a request will cause the application to hang until either the request or the drag service times out; the results can be unpredictable and often both the request and the drag operation will fail.

In the case of CompositeLab, the application asks NXImage to open an file from the **performDragOperation:** method. If the image requires a filter and the filter needs to be launched, this request hangs CompositeLab. However, the same request succeeds the second time as the filter will have been launched by the Workspace after the first attempt times out.

The easiest workaround is to open the image in the **concludeDragOperation:** instead of the **performDragOperation:**. This latter method is invoked while the drag session is still in process, so requests to Workspace hang. The **concludeDragOperation:** method, on the other hand, is called after the drag session is terminated, so the application may contact Workspace during that time.

The following changes will make CompositeLab work correctly. Replace the existing **performDragOperation:** method with the following two methods. Note that although this new **performDragOperation:** doesn't perform the operation, it still validates the dragged data. This is important<the return value of this method determines whether Workspace causes the dragged file(s) to fly back to the source, indicating success or failure to the user.

```
- (BOOL)performDragOperation:(id <NXDraggingInfo>)sender
{
return ([self draggingUpdated:sender] == NX_DragOperationNone) ? NO : YES;
}

- concludeDragOperation:(id <NXDraggingInfo>)sender
{
Pasteboard *pboard = [sender draggingPasteboard];

if (includesType([pboard types], NXColorPboardType)) {
[self doColorDrag:sender];
[sourceColorWell setColor:sourceColor];
[destColorWell setColor:destColor];
[backColorWell setColor:backgroundColor];
} else {
(void)[self changeCustomImageTo:[[NXImage allocFromZone:[self zone]] initFromPasteboard:pboard]];
}
return self;
}
```

If an application wishes to actually open and display images during the drag session, it should ask NXImage if the image can be handled directly or requires a filter service, and open the image only if it falls into the former category. Of course, actually opening and displaying the image during the drag session isn't advisable in the first place as this operation might take a while.

Q: I'm trying to add a cell to a matrix or column of a browser that has already been loaded. I think I'm performing the right steps. I'm even explicitly calling a redisplay but the matrix never shows the new cell. What's going on?

A: When you add cells, the matrix needs to grow to a new size to accommodate them. Most likely the cells are being added, but without resizing the matrix, the new cells are being clipped from view. After adding cells, be sure to call **sizeToCells** (or **sizeToFit** depending on which you want) so the matrix will resize and you can see the new cells.

Here is code fragment that shows adding a cell to an already loaded column of a browser:

```
id matrix,cell;
int row;

matrix = [browser matrixInColumn:0];
```

```
[matrix getNumRows:&row numCols:NULL];
[matrix addRow];
cell = [matrix cellAt:row :0];
[cell setStringValue:"New Cell"];
[cell setLoaded:YES];
[cell setLeaf:YES];
[matrix sizeToCells]; <<--- Don't forget this!!
```

Valid for 1.0, 2.0, 3.0, 3.1

Q: How do I programmatically make a multiple selection in a matrix? I want it to behave exactly as though the user had shift-clicked to select several cells.

A: You must call **setState**: and **highlight:inView:lit**: for each cell that you want to select. Here is a code fragment which will select all the even-numbered cells and deselect all the odd-numbered cells in a matrix.

```
int rows;

[matrix getNumRows:&rows numCols:NULL];
[matrix lockFocus];
while (rows--) {
NXRect rect;
BOOL even = (((rows % 2) == 0) ? 1 : 0);
id cell = [matrix cellAt:rows:0];
[matrix getCellFrame:&rect at:rows :0];
[cell setState:even];
[cell highlight:&rect inView:matrix lit:even];
}
[matrix unlockFocus];
[[matrix window] flushWindow];
```

Valid for 1.0, 2.0, 3.0

Q: What is the difference between a Form and a FormCell? How do I make the correct connections in InterfaceBuilder?

A: A Form is a matrix of FormCells. Even a matrix with only one FormCell is a Form. If you have created a single FormCell with InterfaceBuilder and want to connect to the Form, carefully control-drag to the edge of the cell. When it is outlined in gray, you are connecting to the Form. Control-drag further into cell, and it is outlined in black; now you are connecting to the FormCell. Look at the "Comments" field in the InterfaceBuilder inspector while you are making your connection<it tells you what class the outlet is, for example, "Destination is of the Form Class." The same is true when you are connecting to a Form with more than one FormCell. Drag to the outside edge or in between cells; the form is outlined in gray and you are connecting to the form. Drag to a particular FormCell; it is outlined in black and you are connecting to that FormCell.

Note: In NEXTSTEP Release 3, the "Comments" field in the InterfaceBuilder Inspector has been replaced by a "Connections" field. The information displayed is self-explanatory: The left side shows the outlet name, while the right side shows the class name.

Valid for 1.0, 2.0, 3.0

Q: I am using the function **NXGetNamedObject**(const char * *aname*, id *owner*) to find the **id** of my NXBrowser object. My main program containing the **loadNibSection:owner:** was created by InterfaceBuilder and had NXApp in the **owner:** argument. However, passing NXApp as the owner always returns a nil **id**. What am I doing wrong?

A: By default, InterfaceBuilder assigns the Application object (NXApp) as the owner of a Window, and a View's Window as the owner of that View. Since NXBrowser is a subclass of View, you must use the NXBrowser's Window id instead of NXApp as owner in the function **NXGetNamedObject()**.

Below is a code snippet for illustration:

```
id myWindow, myBrowser;

/* Get the id for the browser's window */
myWindow = NXGetNamedObject("MyWindow", NXApp);
/* Get the id of the browser itself */
myBrowser = NXGetNamedObject("MyBrowser", myWindow);
```

Note that named objects are a big performance loser because of the memory it takes to keep track of all the names of the objects. For this reason, we would recommend that you use **loadNibSection***:owner*:**withNames:***NO* when loading in nib files. Try to use outlets instead of named objects whenever possible.

Valid for 2.0, 3.0

Q: I have subclassed Button and ButtonCell in my application. I am setting the cell class for my button in the **-init:** method for my Button subclass like this:

```
@implementation MyButton : Button

-init
{
[super init];
[MyButton setCellClass: [MyButtonCell class]];
return self;
}
@end
```

However my cell class is not being created and initialized properly. What is going on?

A: **setCellClass:** is a factory method and must occur prior to any instance creation<**init:** is too late. The correct place to do this is in the **+initialize** factory method for your Button subclass (which is called before any instances are created). This problem can occur with all Cell subclasses<such as TextField and NXBrowser. (**+initialize** is an Object factory method; see the Object class specification sheet for more information.)

```
@implementation MyButton : Button
```

```
+initialize
{
[super initialize];
[MyButton setCellClass: [MyButtonCell class]];
return self;
}
@end
```

Valid for 2.0, 3.0

Q: I have a matrix of cells, each 10 pixels high. The matrix lives within a ScrollView, and ten cells are visible at any time. I set my lineScrolling to 10.0, and my pageScrolling to 100.0 (10.0 pixels * 10 cells); line scrolling works fine, but page scrolling (alt-clicking on a scroll arrow) doesn't do what I expect. Instead of scrolling the matrix up or down by ten cells, it only scrolls it by a few pixels (in fact, less than the lineScroll amount). What's happening?

A: The pageScroll value, to quote the documentation, is the ªamount in common before and after the page scroll.º For example, if I set the pageScroll value to 40.0 in the above example, a page scroll will scroll away six of the ten cells currently visible. The 40.0 tells the ScrollView that you want 40.0 pixels of the previously visible contents to remain visible after the page scroll, which translates to 4 cells. With the pageScrolling set to 100.0 in the above example, the ScrollView thinks you want 100.0 pixels of the previously visible contents to appear after page scrolling. Since that's almost all the visible pixels, the matrix scrolls very little. Setting the pageScroll value to 0.0 will cause all ten cells to scroll out of view on a page scroll.

Valid for 1.0, 2.0, 3.0

Q: I would like to have an object in my custom palette do something different when it is unarchived in test mode in Interface Builder. How can I determine if I am in test mode?

A: You can use the **isTestingInterface** method which is defined in the IB (Interface Builder) protocol. See /NextLibrary/Documentation/NextDev/GeneralRef/08_InterfaceBuilder/Protocols/IB.rtf:

Protocol Description

Interface Builder's subclass of the Application class conforms to this protocol. Thus, objects in your custom palette can interact with Interface Builder's main module by sending messages (corresponding to the methods in this protocol) to NXApp.

isTestingInterface
- (BOOL)**isTestingInterface**

Returns YES if Interface Builder is in Test mode.

However, there is a bug with the **isTestingInterface** method in Release 3.1 and after. Even in test mode, **[NXApp isTestingInterface]** always yields **NO** during unarchiving (**read:**,

awake and **finishUnarchiving**). One possible workaround is to delay the isTestingInterface message by calling **perform:with:afterDelay:cancelPrevious:**. Another workaround you can consider is illustrated in Jeff Martin's StringList MiniExample. You can take a look at the StringList MiniExample available via NeXTAnswers, document #1254. The workaround is implemented in the awake method for FilenameList. It is *only* valid in *awake*:

```
// test to see if mainMenu is visible, which it isn't while test
// interface mode is being set up.

if([NXApp conformsTo:@protocol(IB)])
if([[NXApp mainMenu] isVisible]) {
// do something special for test mode
return self;
}
```

Valid for 3.0, 3.1

Q: It seems like the scrollView ignores the frame.origin of its docView. Also, does a ScrollView clip to its update rect(s)?

A: A ScrollView translates the coordinate system of its contentView in response to user movement of the scrollers. Since the frame of the docView is defined in the coordinate system of the contentView (i.e. it's a subview of the contentView), translating the coordinate system of the contentView has the effect of moving the frame, and hence the visible portion of the docView.

When you do a **setDocView**: the system translates the coordinate system of the contentView so that the contentView's bounds.origin is the same as the frame.origin of the docView. For example: if the frame.origin of your docView is {100.0,100.0}, the bounds.origin of the contentView will be {100.0,100.0} as well.

So the ScrollView does pay attention to what the frame.origin of the docView is, but it doesn't really matter what it is, at least initially.

User code really shouldn't make changes to the frame of the docView as it is being managed by its superview (a ClipView). To achieve scrolling use the - **rawScroll:** method.

No, the drawing is not clipped to the update rects; however, you can restrict the area being redrawn yourself by using **PSrectclip**() or **NXRectClip**() in your **drawSelf**:: method.

Valid for 1.0, 2.0, 3.0

Q: In my application I have subclassed the Text object and called it SubText. I have a ScrollView which I installed using InterfaceBuilder which has a standard Text object as its docView. I wish to replace that Text object with my own but I wish to maintain all the same behaviors<with a vertical scrollbar and text which resizes properly. How do I do that?

A: The following code snippet creates an instance of your new subclass of Text and inserts it into the docView of the ScrollView. The old Text object is then freed. In the code sample

``theSV'' is an outlet connected to the ScrollView. Because an existing ScrollView is used, certain setups are not required. See Chapter 9, page 35 of the Concepts volume of the 1.0 Technical Documentation for more information on setting up a brand-new ScrollView.

The key here that many people miss is to set the min size and max size on the Text object.

```
id stdDoc;
NXRect r;

/* Measure the old doc view. */
stdDoc = [theSV docView];
[stdDoc getFrame:&r];

[theSV setVertScrollerRequired:YES];
[theSV setHorizScrollerRequired:NO];
[theSV setDynamicScrolling:YES];

/* Instantiate the new Text object */
#ifdef 1.0
newDoc = [SubText newFrame:&r];
#else /* 2.0 or 3.0 */
newDoc = [[SubText alloc] initFrame: &r];
#endif
[newDoc moveTo:0.0:0.0];
[newDoc notifyAncestorWhenFrameChanged: YES];
[newDoc setVertResizable:YES];
[newDoc setSelectable:YES];
[newDoc setEditable: YES];
[newDoc setAutosizing:NX_WIDTHSIZABLE];
[newDoc setMinSize:&r.size];
r.size.height = 1.0e30;
[newDoc setMaxSize:&r.size];
[theSV setDocView:newDoc];

/* Free the old Text object */
[stdDoc free];
```

Note that the ifdef for 1.0 is for illustration purposes only and is NOT defined in any NeXTstep include file.

Valid for 1.0, 2.0, 3.0

NeXTSTEP NT Printer Patch Overview

This document describes a problem printing to a Windows NT 3.1 Postscript printer from NeXTSTEP and provides a patch to work around the problem.
This article has been archived and is no longer updated by Apple.

Question

When I print from NEXTSTEP to a a remote Postscript printer on a NT 3.1 system which is using the Microsoft TCP/IP Printing software, the file prints out as ascii text containing Postscript source code and is not interpreted into the correct postscript image. What causes this and is there a way to fix the problem?

Answer

This problem is caused by a bug in the NT 3.1 system. A text file that starts with the characters %! should be interpreted by a Postscript printer as Postscript code and the printer should process the file into a Postscript image. The NT driver seems to set the printer mode to ignore this. A workaround to this problem is to use the **lpr -l** option. This option tells **lpr** to print the source literally and preserves in any control characters. This will cause NT to print the file correctly. This workaround can be made transparent to a users printing from NEXTSTEP applications by using a *wrapper script* in place of the **/usr/ucb/lpr** command. The wrapper script just adds the **-l** option and runs the real **lpr,** passing along any arguments.

An **Installer** Package has been create to install a this work around on your system. Just install the package as root on each system that prints to a remote Postscript printer on a NT 3.1 system. This will fix the problem with printing to NT 3.1. It does not effect printing to Next Laser Printers and also should not effect printing to any other type of printers, however, **faxing will no long work** correctly when the patch is installed. Faxes will be sent to the currently selected printer instead of the Fax modem.

You can download the patch from:

ftp://ftp.info.apple.com/Apple_Support_Area/Apple_Software_Updates/MultiCountry/Enterprise/nextstep/patches/3.3/NT_Printing_Patch.compress

NEXTSTEP uucp Q&A

Disclaimer

This document pertains to the NeXTSTEP operating system, which is no longer a supported product of Apple Computer. This information is provided only as a convenience to our customers who have not yet upgraded their systems, and may not apply to OPENSTEP, WebObjects, or any other product of Apple Enterprise Software. Some questions in this Q&A document may not apply to version 3.3 or to any given specific version of NeXTSTEP.
This article has been archived and is no longer updated by Apple.

Q: I'm running **uucico** and all I get is "bus error"<no other messages, even with debugging turned on to any level. What might be wrong?

A: Ensure that the **uucico** program can access the UUCP spool directory. Since the program is (supposed to be) SetUID uucp and SetGID daemon, this means the uucp user must be able to read and write the directory.

If you examine the files using the UNIX **ls**(1) command, you should see the following (dates might be different, and the size of the spool directory might be different):

```
localhost [/me]-7% ls -ldg /usr/lib/uucp/uucico /usr/spool/uucp
---s--s--x 1 uucp daemon 90112 Nov 11 17:25 /usr/lib/uucp/uucico*
drwxr-xr-x 14 uucp daemon 1024 Dec 22 03:30 /usr/spool/uucp/
```

If you see different results, and you're not *absolutely certain* why they're different, you can set things right with the following commands:

```
localhost [/me]-7% su
localhost-1# chown uucp.daemon /usr/lib/uucp/uucico /usr/spool/uucp
localhost-2# chmod 755 /usr/spool/uucp
localhost-3# chmod 6111 /usr/lib/uucp/uucico
```

One other thing to note: the output of the **ls** on **uucico** is the same whether the owner and the group have execute permission or not. In UNIX parlance, the mode display in the **ls** is the same whether the numeric mode is 6001, 6011, or 6111. Be *sure* it's 6111: SetUID, SetGID, and execute for user, group, and other.

By the way, the rest of the commands in the UUCP suite are likely subject to the same limitations. We have verified that **uucp** behaves like **uucico** in this situation; we have not tested the rest of the suite, but anything which needs access to the spool directory are suspect. For completeness, here's another **ls -lg**:

```
localhost [/me]-8% ls -lg /usr/bin/uu* /usr/lib/uucp/uu*
---s--s--x 1 uucp daemon 24576 Nov 11 17:25 /usr/bin/uucp*
-rwxr-xr-x 1 uucp daemon 16384 Nov 11 17:26 /usr/bin/uudecode*
-rwxr-xr-x 1 uucp daemon 2984 Nov 11 17:26 /usr/bin/uuencode*
---s--s--x 1 uucp daemon 4620 Nov 11 17:25 /usr/bin/uulog*
---s--s--x 1 uucp daemon 5776 Nov 11 17:25 /usr/bin/uuname*
---s--s--x 1 uucp daemon 24576 Nov 11 17:26 /usr/bin/uupoll*
---s--s--x 1 uucp daemon 8716 Nov 11 17:26 /usr/bin/uuq*
---s--s--x 2 uucp daemon 3548 Nov 11 17:26 /usr/bin/uusend*
---s--s--x 1 uucp daemon 4260 Nov 11 17:26 /usr/bin/uusnap*
---s--s--x 1 uucp daemon 24576 Nov 11 17:25 /usr/bin/uux*
---s--s--x 1 uucp daemon 90112 Nov 11 17:25 /usr/lib/uucp/uucico*
---s--s--x 1 uucp daemon 11136 Nov 11 17:25 /usr/lib/uucp/uuclean*
---s--s--- 1 uucp daemon 32768 Nov 11 17:26 /usr/lib/uucp/uuxqt*
```

Q: uucico is being uncooperative. Specifically, if someone polls my machine, my machine hangs up the phone (the other side typically sees this after the second

imsg looking for SYNC<

message in the debug output). When I poll that same machine, uucico provides a core dump, after a segmentation fault. What's stranger still is that polling *some* machines works fine, and those machines can poll mine!

Q: uucico is crashing when it tries to transfer files other than mail. Mail comes through fine, but a file transfer won't. What's wrong?

A: The likely problem is that you have improperly formatted UUCP configuration files. For example, blank lines in your L.sys file can cause the first symptom, and malformed lines in your USERFILE can cause the second.. The UUCP system can't handle these.

In the case of the blank L.sys line, if the line is entirely empty<no spaces, no tabs, just empty<uucico works fine. However, if the line contains only whitespace<spaces and tabs<then uucico crashes. Remove the blank lines, or, if you like white space in your L.sys file, replace the blank lines with otherwise-empty comment lines.

In addition, if expected fields are missing, uucico has been known to crash. For example, the following L.sys entry will crash uucico:

```
π \\
"" ATdt555-1212 \\
ogin:~20- -ogin:- -ogin: name \\
ssword: YouKnowWhat
```

What was *desired* in this case was to send a newline if the prompt **ogin:** was not received. What happened instead is that uucico was looking for the next *expect* string in the *expect-send* sequence, and it wasn't there. To accomplish this, use the following instead:

```
π \\
"" ATdt555-1212 \\
ogin:~20-CR-ogin:-CR-ogin: name \\
ssword: YouKnowWhat
```

In the case of a malformed USERFILE, check for lines with a missing space. The format of USERFILE is

[user],[system] directory

You *must* have the space between the user,system and the directory. (Yes, user and system are both optional. The comma between them and the space following them are not.)

One other thing which can cause uucico to fail (silently on the remote, with a bus error locally) is if the program<which runs SetUID uucp and SetGID daemon<does not have appropriate access to the UUCP spool directory, /usr/spool/uucp. Ensure that the user **uucp** can read, write, and search (ªexecuteº) the spool directory. Recommended permissions are 755 (read, write, execute for the user; read, execute for the group; read, execute for others).

Q: uucico is being uncooperative. Specifically, if someone polls my machine, my machine

hangs up the phone (the other side typically sees this after the second

imsg looking for SYNC<

message in the debug output). When I poll that same machine, uucico provides a core dump, after a segmentation fault. What's stranger still is that polling *some* machines works fine, and those machines can poll mine!

Q: uucico is crashing when it tries to transfer files other than mail. Mail comes through fine, but a file transfer won't. What's wrong?

A: The likely problem is that you have improperly formatted UUCP configuration files. For example, blank lines in your L.sys file can cause the first symptom, and malformed lines in your USERFILE can cause the second.. The UUCP system can't handle these.

In the case of the blank L.sys line, if the line is entirely empty<no spaces, no tabs, just empty<uucico works fine. However, if the line contains only whitespace<spaces and tabs<then uucico crashes. Remove the blank lines, or, if you like white space in your L.sys file, replace the blank lines with otherwise-empty comment lines.

In addition, if expected fields are missing, uucico has been known to crash. For example, the following L.sys entry will crash uucico:

```
π \\
"" ATdt555-1212 \\
ogin:~20- -ogin:- -ogin: name \\
ssword: YouKnowWhat
```

What was *desired* in this case was to send a newline if the prompt **ogin:** was not received. What happened instead is that uucico was looking for the next *expect* string in the *expect-send* sequence, and it wasn't there. To accomplish this, use the following instead:

```
π \\
"" ATdt555-1212 \\
ogin:~20-CR-ogin:-CR-ogin: name \\
ssword: YouKnowWhat
```

In the case of a malformed USERFILE, check for lines with a missing space. The format of USERFILE is

[user],[system] directory

You *must* have the space between the user,system and the directory. (Yes, user and system are both optional. The comma between them and the space following them are not.)

One other thing which can cause uucico to fail (silently on the remote, with a bus error locally) is if the program<which runs SetUID uucp and SetGID daemon<does not have appropriate access to the UUCP spool directory, /usr/spool/uucp. Ensure that the user **uucp** can read, write, and search (ªexecuteº) the spool directory. Recommended permissions are 755 (read, write, execute for the user; read, execute for the group; read, execute for others).

Q: What are are the various UUCP (**uucp**, **uucico**, **uux**, **uuxqt**) debug messages, their

levels, and the modules from which they are emitted?

A: Following are the debug messages. There are two lists, separated by a line of em-dashes (<); search for an em-dash or for the word Module. (Note that the second list starts about half-way into the fileπ) The first is the debug messages sorted by level, the second is the messages sorted by module. (The messages are displayed by the UUCP System components when they are given the -x option.)

These lists are based on the Release 2 sources. The Release 1 lists differ only slightly.

UUCP System Debug Messages, Sorted by Level

```
1 anlwrk.c "opendir(%s) FAILS\\n",subdir(dir,pre[0])
1 anlwrk.c "opendir(%s) FAILS\\n",subdir(dir,pre[0])
1 cds224.c "timeout concord open\\n", ""
1 chkpth.c "*** Userpath malloc failed\\n", 0
1 chkpth.c "*** Userpath malloc failed\\n", 0

Q: I'm sending mail via UUCP. Things work *great* from my mail server (which is also my UUCP gateway). From a mail client, though, I get error messages indicating the remote UUCP machine is unknown. The bounce message looks like this:

Date: Mon, 13 Apr 92 13:11:11 CDT
From: Mailer-Agent (NeXT Mail Agent)
Subject: Returned mail: Unable to deliver mail
To: amm

----- Transcript of session follows -----
554 rhino!sandy... Never heard of UUCP host rhino

----- Unsent message follows -----
π

What's going on here?

A: One likely source of the problem is that **sendmail** might not have an uptodate notion of the known UUCP connections. If you've added the remote machine (**rhino** in the example, above) and neither rebooted the server nor restarted the **sendmail** process on the server, then **sendmail** doesn't know about the new connection.

A **sendmail** daemon process is started when the system boots, by **/etc/rc**. When **sendmail** starts up, it runs the command **uuname** to determine the known UUCP connections. (At least, it does this with all the standard configuration files NeXT ships.) The **uuname** command is run *only once*. It is this **sendmail** daemon that handles all the mail coming from the client machines.

So, why does mail originating locally work? A new **sendmail** process is run for each locally-originating message; this new **sendmail** process runs its own instance of **uuname** when it starts. Since **uuname** for the new **sendmail** process has been run after the new system's addition to **L.sys**, the new **sendmail** knows about the new system.

Q: UUCP is complaining about my mail missing newlines and mail is bouncing. What can I do?

A: If the bounced mail has errors like the example below, the problem can be fixed by editing your UUCP mailer specification in your sendmail.cf.

```
> From @scapa.cs.ubert.ca:me@uaneuro Thu Jun 6 11:32:04 1991
> Message-Id: <9106061732.AA10617@namao.ucs.ubert.ca>
> Date: Thu, 6 Jun 1991 12:34:01 -0600
> Illegal-Object: Syntax error in From: address found on scapa.cs.ubert.ca:
> From: uaneuro!me (My Account)
> ^-missing newline (LF)
> Illegal-Object: Syntax error in Message-Id: value found on scapa.cs.ubert.ca:
> Message-Id: <9106061834.AA00160@uaneuro>
> ^-missing newline (LF)
> Illegal-Object: Syntax error in To: address found on scapa.cs.ubert.ca:
> To: namao.ucs.ubert.ca!thorjman
> ^-missing newline (LF)
> From: me@uaneuro.uucp
> To: thorjman@namao.ucs.ubert.ca
> Subject: test 2 (non-NeXT)
```

The fix is to add a new definition of the end of line character to the UUCP mailer definition. Add the text shown in bold to the sendmail.cf file in use on your uucp mail hub machine.

```
###################################################################
#####
##### UUCP Mailer specification
#####
Muucp, P=/usr/bin/uux, F=msDFMhuU, S=13, R=23, E=\\n,
A=uux - -r $h!rmail ($u)
```

Q: I'm trying to connect to another machine using UUCP over the ethernet. When I run **uucico** in debug mode (**-x99**), I get the message

```
tcpopen failed: errno 61
root rhino (11/13-14:39-2883) FAILED (Connection refused)
```

My **L.sys** and **USERFILE** files are correct; the remote machine's, likewise. I have an entry for **uucp** in my **/services** directory in NetInfo:

```
myhost:22# niutil -read . /services/uucp
port: 540
protocol: tcp
```

name: uucp uucpd

What's wrong?

A: You also need to enable **uucp** in the file **/etc/inetd.conf**. We ship the system with the line in the file, but commented out:

```
# Run as user "uucp" if you don't want uucpd's wtmp entries.
# uucp stream tcp nowait root /usr/etc/uucpd uucpd
```

Just uncomment the ª uucp streamº line, send **inetd** a SIGHUP, and you're all set. See the inetd(8) UNIX Manual Page for details on the format of **inetd.conf**.

By the way, each step accomplished (**L.sys** and **USERFILE** being correct on both machines, a **uucp** entry in **/services** in NetInfo) is necessary in addition to the modification to **inetd.conf**.

Note also that in Release 1.0 and Release 1.0a a TCP-based UUCP connection does not work, even if you accomplish everything mentioned in this document. This is because of a bug, fixed in Release 2.

PDO 4.2 Installation Q&A

This article contains questions and answers on PDO 4.2 installation issues.
This article has been archived and is no longer updated by Apple.

Q: What does PDO do to the header files on my system and will this affect my other developing environments?

A: The header files on some systems are incompatible with the ANSI C standard. The PDO install script runs the "fixincludes" script, provided by GNU with gcc, which fixes up some of these "broken" headers so they work correctly with ANSI C. The changes are syntactical in nature only; it doesn't add or remove any definitions. It also ensures that the standard ANSI header files are present (such as stdarg.h).

The "fixincludes" script does not modify directly any of the system header files. It makes a copy of each header it needs to fix (in /usr/NextDeveloper/lib/gcc-lib/`arch`/2.5.8/include) and modifies the copy. Gcc searches this directory before it searches the system directories, so it picks up the altered headers first. Since "fixincludes" makes a copy of the headers to a directory only gcc searches, this has no impact on any other compilers which might be installed.

NEXTSTEP 3.3 Disk and Filesystem Q&A

Disclaimer

This document pertains to the NeXTSTEP operating system, which is no longer a supported product of Apple Computer. This information is provided only as a convenience to our customers who have not yet upgraded their systems, and may not apply to OPENSTEP, WebObjects, or any other product of Apple Enterprise Software. Some questions in this Q&A document may not apply to version 3.3 or to any given specific version of NeXTSTEP.
This article has been archived and is no longer updated by Apple.

Q: How do I put a recycler on my external hard disk?

Q: My new external disk displays a panel indicating "No recycler for device..."

A: In order to have recycler on an external disk, you must have a .NextTrash directory at the mount point for the drive. As an example, here is how you would create a recycler for an external disk mounted as /archive (issue the following commands as root in a Terminal window):

localhost# **cd /archive**
localhost# **df .**
Filesystem kbytes used avail capacity Mounted on
/dev/sd2b 216311 152584 42095 78% /archive
localhost# **mkdir .NextTrash**
localhost# **chown root.wheel .NextTrash**
localhost# **chmod 1777 .NextTrash**
localhost# **ls -ldg .NextTrash**
drwxrwxrwt 19 root wheel 1024 Sep 30 10:42 .NextTrash/

After completing these steps, you'll need to reboot the system for the new recycler to be properly recognized.

Q: Are file system quotas supported by NeXT software?

A: No. Quotas are not supported by NEXTSTEP.

Q: Why does fcntl(fd, F_SETLK, &lockstruct) give EINVAL? What is the preferred method of file locking?

A: The current release of Sun's NFS file system has a number of problems regarding file locking. Sun has implemented a "first crack" at solving the problems associated with extending Unix's file locking to NFS. NeXT decided, upon looking at this, that there were too many hidden deadlock conditions inherent in the implementation to release. Instead, the current version of fcntl(2) will fail with EINVAL if the directives F_GETLK or F_SETLK are used. These directives will work when a new version of NFS file locking is available, in our 4.0 release.

In the mean time, if a file locking system is necessary for your application, the best system to use is to write out a file whenever your application accesses a file for writing. The easiest thing to do is to create a file of the same name with an added extension, like "LCK" for instance. Your application should check to see if this file exists before opening a file, and create the lock file, if one doesn't exist.

Here's one idea: if you open(2) a file with both CREATE and EXCLUSIVE turned on, then open(2) will return an error if the file exists, and will create the file if it doesn't. Something like

```
#include <sys/file.h>
int fd;

fd = open(lockfile, O_CREAT | O_EXCL, 0600);

if (fd < 0) { /* Something didn't work */
if (errno != EEXIST) { /* Real error occurred */
perror("Open failed");
exit(1);
}
else { /* Lock file is there */
/* await lock release */
}
}
else /* Things are OK */
```

This still has some problems when systems crash with files open, or the if the Workspace exits with your application still running. To deal with this, your application should erase these lock files (with the unlink(2) system call, for example) in an appDidTerminate: method. Also, when one of these lock files exist, you should display an alert panel asking if the user would like to override the lock.

For applications that run on a single machine (without any network file access) you can use flock(2)if you are concerned that your application may be run multiple times on the same machine. This scheme works for network files too, when that support is added.

Note: the fcntl(2) directives not associated with file locking:

```
F_{DUP,SET,GET}FD
F_{GET,SET}FL
F_{GET,SET}OWN
```

work fine.

Q: To where is the /mach symlink resolved when netbooting (or any other sort of booting)?

A: To the path of the kernel booted; typically, this is:

```
/private/tftpboot/mach
```

though it could be rather anything, depending on what was in the server's bootptab and NetInfo databases. By default, this file is itself a symlink, to /sdmach.

Default boot devices and $BOOTFILE values are

SCSI sdmach
OD odmach
Net /private/tftpboot/mach

Note that if the user booted with a command such as

```
bsd()MyMach
```

then $BOOTFILE will resolve to MyMach.

Q: I'm using rdist to do remote software distribution, or to copy files from an optical disk to my hard disk. But, rdist gives the error "permission denied." What's wrong?

A: Be sure the machine from which you're doing the rdist is in the .rhosts file of the target machine (this file contains a list of trusted remote hosts). /.rhosts is consulted if the rdist is being run as root. In other cases, the .rhosts file in the user's home directory and the hosts.equiv file are consulted, in the same manner as for rcp and rsh. (Note that hosts.equiv is NOT consulted when the rdist is being run as root.)

Q: I changed **/etc/fstab**, and now NEXTSTEP won't boot. If I boot the system in single-user mode, I can't edit **/etc/fstab** to fix it because the file system is read-only. What do I do to fix it?

A: The start-up script **/etc/rc.boot** makes the root filesystem read-write with the command:

```
mount -o remount /
```

The **mount** command looks in **/etc/fstab** for an entry that describes "/". It should find a line like:

```
/dev/sd0a / 4.3 rw,noquota,noauto 0 1
```

This means that the filesystem on the device sd0a should be mounted as the root ("/") filesystem. If this line in the **/etc/fstab** file is missing, incorrect, or damaged, the mount command fails. You are left with a read-only root filesystem.

The solution is to re-mount the root file system with the shell command:

```
# mount -o remount /dev/sd0a /
```

In this form, you are telling mount exactly which device to use, so it doesn't look in **/etc/fstab** and get confused. Once you have the root filesystem mounted read-write, fix it with a text editor (don't include any blank lines) or get a copy of a default **/etc/fstab**. You can find default copies in **/usr/template/client**. i.e.:

```
# cp /usr/template/client/etc/fstab.sd330 /etc/fstab
```

Then shut down and reboot your system:

```
# reboot
```

Q: Why is the ``high water mark" in my **/etc/swaptab** ignored?

A: This is probably due to an extra space in **/etc/swaptab**. The format of this file must be exactly as in **swaptab(5)**, without spaces after the commas. Thus

```
#
# /etc/swaptab
#
/private/vm/swapfile lowat=20971520,hiwat=73400320 # 20/70 MB
```

works as expected, but in

```
#
# /etc/swaptab
#
/private/vm/swapfile lowat=20971520, hiwat=73400320 # 20/70 MB
```

the **hiwat** is ignored (note the space after the first comma).

Q: My machine won't swap to my swapdisk (SCSI address 6). However, I think this used to work.

A: You may have a removable media device at a lower SCSI address than your swap disk. Devices with no media in them cannot return a disk label, causing **checkswap** to return FSR_NONE. The file /etc/rc.swap has a line

```
case $swapstatus in
0)
# No such disk was actually connected.
break;
;;
```

This can be fixed by removing the line with *break* in it. You end up with:

```
case $swapstatus in
0)
# No such disk was actually connected.
;;
```

The downside is that the script always scans for all SCSI devices looking for a swap device.

Q: What is the size of the swapfile for NEXTSTEP?

A: The size of the swapfile depends on the parameters set up in the **/etc/swaptab** configuration file and the demand for paging on the system. The swapfile dynamically grows on demand; the demand for swapping depends on the memory needs of the running applications, and the size of the ªrealº memory (the more real memory the less the demand for paging space).

The **swaptab** file looks like this:

```
#
# /etc/swaptab
#
/private/vm/swapfile lowat=20971520 # 20 Meg low water mark
```

This tells the system to use the file **/private/vm/swapfile** for swapping. It also specifies the parameter **lowat=20971520**, the ªlow water mark.º This low water mark is the smallest size to which the file shrinks. The paging file then grows as needed to meet demand.

A **hiwat=*n*** parameter may be used in the **swaptab** to set a limit on how large this file

grows.

Q: What size is the **swapfile** when a fresh copy of NEXTSTEP is installed ?

A: It starts out at 16MB out of the box. It should never get smaller, since this the default size of the lowat mark in /etc/swaptab.

Q: Will the **swapfile** get smaller (if above the low water mark) while the system is running, or is it reset only upon reboot?

A: The swapfile works in a stack-oriented manner<it shrinks only if the system detects that all pages above a certain address are unallocated. This rarely occurs. Consider launching a 4MB application which is completely paged out followed by one more page owned by some other application in the system. Even if the 4MB is freed the swapfile cannot be truncated until that extra page is freed. What generally happens is that long-running applications allocate a few pages at the high addresses, and **swapfile** apparently never shrinks.

During a reboot when paging is turned on (by the invocation of **mach_swapon**), the **swapfile** is immediately truncated to the minimum value.

Note: Despite the file being called the **swapfile**, NEXTSTEP uses pure demand-paged memory management. mach_swapon(8) tells the kernel to initiate paging.

Q: Why does BuildDisk.app indicate ªpermission deniedº and die? Doesn't it run as root?

A: One possible cause of this situation is related to running BuildDisk.app while your system is connected to a network. BuildDisk.app tries to ensure that what it's building will fit on the target disk. To do this, it calculates the size of each directory to be loaded. If, for example, you have **/NextDeveloper/Examples** imported from an NFS server, and, if there's a **.NextTrash** directory in that directory, the **root** user might not be able to see what's inside in order to determine the size.

Whenever possible, run BuildDisk.app on a system that's *disconnected* from the network.

If you *must* be connected to the network (e.g., if you're running BuildDisk.app on a NeXTstation that's NetBooted), and if you get a message like the above, go to the machine that's serving the flagged directory and remove the **.NextTrash** directory and its subdirectories (or whatever other directory is giving you problems). If removing the directory is inappropriate, either grant everyone read permission, or export the file system (via **exportfs** and the **/etc/exports** file; see the UNIX Manual Pages or the *NeXT Network and System Administration* manual) to grant root access as necessary to the NetBoot client.

It's also possible that you'll run out of space on the target machine if you're importing large directories from an NFS server.

Q: I want to customize the icon displayed for a directory in the Workspace File Viewer. How can I do this?

A: The Workspace Manager looks for a file called **.dir.tiff** in the directory. It uses this in place of the usual icon when displaying that directory in the Viewer. You may also want to place a file called **.opendir.tiff** in the directory. This is used in place of the ªopen folderº icon which is displayed when you drag new files to that directory. For best results, the tiff files should be 48 x 48 pixels square. The **.dir.tiff** icon is also used by Digital Librarian to represent the directory if you use it as a target.

For fun, you can put a **.dir.tiff** and a **.opendir.tiff** file in your home directory and replace the little house with something more representative of your personality!

NEXTSTEP 3.3 Network and CD Boot Q&A

Disclaimer

This document pertains to the NeXTSTEP operating system, which is no longer a supported product of Apple Computer. This information is provided only as a convenience to our customers who have not yet upgraded their systems, and may not apply to OPENSTEP, WebObjects, or any other product of Apple Enterprise Software. Some questions in this Q&A document may not apply to version 3.3 or to any given specific version of NeXTSTEP.
This article has been archived and is no longer updated by Apple.
Q: Can I boot from a release CD-ROM disc and not be required to initialize or upgrade the hard disk drive?

A: Yes. You will have the ability to view, copy, move, etc. files, run programs, and perform other similar operations. While you can't boot a full NEXTSTEP environment (Workspace Manager, et al.), you can boot single-user from the CD-ROM installation disc.

Intel (i386) architecture

Insert the CD-ROM disc and the boot floppy and boot the system. On the i386 architecture, booting starts from the floppy drive and continues to the CD-ROM.

At the boot: prompt type:
boot: **mach_kernel -s**
Follow any instructions (it may appear as though an install or upgrade is being performed; be patient) until the UNIX command line prompt is displayed. If you are asked which disk to install NEXTSTEP to, then you must have made a mistake at the boot prompt.

NeXT (m68k) architecture

Use <Command><Command><~> after power-on to get to the ROM monitor and type the following:

For Non-Turbo systems with internal floppy

Insert the boot floppy and type:
NeXT> **bfd -s**

For Non-Turbo systems with SCSI floppy

Insert the boot floppy and type:
NeXT> **bsd(*n*,0,0) sdmach -s rootdev=sd*n***
Where n is the unit number of the floppy drive. In this scenario, it may be helpful to have the CD-ROM drive set to a higher SCSI address than the SCSI floppy.

For Turbo systems

Turbo systems have the ability to boot directly off the CD-ROM drive without assistance from the floppy drive.
NeXT> **bsd(*n*,0,0) sdmach -s rootdev=sd*n***
Where n is the unit number of the CD-ROM drive.

All architectures

Mounting a hard disk
Note that when booted single user from a CD-ROM, the file system is mounted read-only. Certain functions may not be available. This state can be somewhat alleviated by mounting /tmp on another available disk. Use the -n option with the mount command to prevent writing to /etc/mtab (which fails, obviously). As an example:

mount -n /dev/<*device*> /tmp

where <device> is the disk you wish to mount (eg. sd0a, hd0a).

Once in single-user mode, you can still run the CD-ROM build disk scripts by running the rc scripts:
sh /etc/rc

Copying & Editing.

Under Release 3.3, you can use ditto(8) to perform a copy of an entire directory, preserving links and setuid and setgid

modes. pico(1) is a simple text editor that ships with 3.3 for those that find vi(1) confusing. See the man pages for information on these commands.

Q: From where does a netboot server (bootpd) get its ªserved kernelº information?

A: The netboot server gets its kernel information from two sources:

· NetInfo and
· /etc/bootptab.

(Yes, from both. Even if NetInfo is running, the file is consulted.)

There are two types of bootpd information: global (i.e., for all netboot clients) and local (i.e., for a specific client). The global information is read from the file /etc/bootptab; the local information comes from NetInfo (the /machines/client directory).

There are two pieces of global information: the tftpboot root directory, and the default kernel to be served. [What's tftpboot? It's the file transfer mechanism used for netbooting < trivial file transfer protocol boot.] All kernels which can be booted must be located in the tftpboot root directory, which is typically /private/tftpboot on our system. Any pathname given, either for the default kernel or for a per-client kernel, is relative to the tftpboot root directory; further, that directory is considered as the root directory for the tftpboot process, so a path like /sdmach will be interpreted as /private/tftpboot/sdmach. (Why is this done? Security: it prevents booting arbitrary files from the boot server.)

Then there's the local information: a host type, ethernet address, IP address, and bootfile. These are all obtained from NetInfo. Note that, although the host type appears in bootptab, it is not present in NetInfo; if an niload(8) is done, it MUST have the value 1 (else niload will yield an error). If you nidump bootptab, a 1 will be provided in the field.

Now, the stage is set for explaining how the netboot sequence occurs, regarding the boot protocol.

The following paragraph describes the boot sequence from the server's perspective:

1. A client sends a BOOTP broadcast, asking for the file boot (the name is in the PROM). This is the request for the ªblk0 loader,º also known as the ªbootstrap loader.º The server notices same.
2. The server then checks in NetInfo to determine if the ethernet address in the BOOTP request is known. The NetInfo hierarchy is searched, starting with the local domain, looking for a /machines entry with an en_address property whose value matches the address of the broadcaster.
3. If the ethernet address is known, the server responds to the client with information including the path to the bootstrap loader. This path is comprised of two components: the directory, and the file name. The directory is determined from /etc/bootptab (yes, even if NetInfo is running); this is the ªtftpboot rootº directory. The file name was specified by the broadcaster (the client) in 1, above, as boot.
4. A request from the client to transfer the bootstrap loader is received; the loader is sent back, using TFTP.
5. Another BOOTP request is received, this time for the pathname to the kernel. The path is sent, determined from a combination of NetInfo and /etc/bootptab. Specifically, the tftpboot root directory (at the top of the tree from which kernels can be obtained) is found in bootptab, as is the default kernel to be sent. The kernel to be sent can be overridden in NetInfo: the bootfile property in the client's directory in the /machines directory specifies this. (Domains are searched on the server, starting with the server's local domain, continuing up the NetInfo domain hierarchy.) It can also be overridden by the client, in the boot command specified [e.g., ben()new_mach]; note that any explicit path given for a kernel will be relative to the tftpboot root directory.

Transfer of the kernel, using TFTP, completes this phase of the boot sequence.

One other note. This notion of ªtftpboot rootº is a bit unusual. A chroot(2) is only effected during the actual transfer. If a path such as ../MyMach (e.g., ben()../MyMach) is given for the kernel, strange things will result. Specifically (assuming the normal tftpboot root) /private/MyMach (that is, /private/tftpboot/../MyMach) must exist, and MyMach must exist in the tftpboot root directory. It is the latter of these which will actually be TFTPed to the client. Note also that the kernel file name shouldn't have any dash characters (-) in it: the dash is used by the PROM's boot command to denote arguments to be passed to the booted kernel.

Q: I'm booting a NetBoot client<or, rather, trying to. But it keeps looping through the reboot, getting only as far as allocating a swapfile. What's wrong?

A: One cause of this could be that the client's private partition is not exported correctly. The private partition must be exported with root access for the client. Even when **/etc/exports** indicates a proper entry, if a parent directory of the client's private partition is a) on the same filesystem, and b) exported *without* root access for the client, then the client's private partition is not exported with root access for the client (note that exports information is stored in the NetInfo database in Release 3 and later; see the NetInfo exports directory and NFSManager.app).

A situation where this readily occurs is when you're trying to use a machine with one partition on the disk as the NetBoot server. This is *not* a supported configuration. In this situation, the **exports** file might look like:

```
/ -access=rhino:cockatoo
/clients/rhino -access=rhino,root=rhino
/clients/cockatoo -access=cockatoo,root=cockatoo
```

If the disk has only one partition then the clients' partitions is *not* exported with root access for the client. To fix this, change the **exports** file to:

```
/ -access=rhino:cockatoo,root=rhino:cockatoo
```

If you want to leave the explicit lines for the two client partitions, that causes no harm, and might help avoid a problem if you ever set things up on a two-partition disk.

Q: The commands *w* and *netstat* return "no namelist" on a netbooted client. What's going on?

A: The *w* command prints a summary of the current activity on the system, including what each user is doing, The *netstat* command symbolically displays the contents of various network-related data structures. Both of those commands examine the system namelist kept in the file */mach* (the kernel). The kernel namelist contains the current system addresses. On a netbooted client, */mach* references the path */clients/client/tftpboot/mach*. If this file is not present, any command that uses the kernel's namelist cannot complete successfully and returns a "no namelist" error.

To fix the problem, make a symbolic link to the kernel like this:

· On the netboot server, launch the Terminal application as root
· Run the following command:

```
server#ln -s /sdmach /clients/client/tftpboot/mach
```

where client is the name of your netbooted client.

w and *netstat* now return the correct data on your netbooted client. You need to repeat this procedure for each netbooted client.

This only applies if the netboot server and client are running the same version of the OS, on the same hardware architecture.

NeXTSTEP Applications and Tools Q&A

Disclaimer

This document pertains to the NeXTSTEP operating system, which is no longer a supported product of Apple Computer. This information is provided only as a convenience to our customers who have not yet upgraded their systems, and may not apply to OPENSTEP, WebObjects, or any other product of Apple Enterprise Software. Some questions in this Q&A document may not apply to version 3.3 or to any given specific version of NeXTSTEP.
This article has been archived and is no longer updated by Apple.

Q: When I attempt to print an Edit file from a shell, my output consists of several very long lines (i.e., it does not word wrap).

A: Edit does not save return characters in its files, but uses the word wrap capability of the AppKit's Text object to resize the lines to fit the window. You can use the UNIX command *fmt* to break the file into shorter lines.

% fmt *filename* | lpr

Also, the *enscript* command will convert text files to PostScript format for printing.
See the man pages for *fmt* and *enscript* for more information.

Q: How can I tell how much WindowServer memory my application is using? Some Application Kit programs can use a significant number of windows and bitmaps, and the memory used in these cases isn't easy to trace.

A: Use ProcessMonitor.app located in /NextDeveloper/Apps. This application allows you to measure and analyze your application's memory usage. In particular, the Display Postscript Inspector shows the amount of backing store and virtual memory used by your Application. A monitor panel displays this information in graphical form. For further information please refer to the documentation in /NextLibrary/Documentation/NextDev/DevTools/09_ProcessMonitor/ProcessMonitor.rtfd (for Release 3) or /NextLibrary/Documentation/NextDev/DevTools/04_DevApps/ProcessMonitor.rtfd (for Release 2).

Q: How can a NEXTSTEP application run windows on the WindowServer of a remote host?

A: Someone must be logged on to the host you would like the windows to appear on (the "target" host). The user that is logged on must have Public Window Server access on. This gives permission for a remote host to establish a connection to its WindowServer. Public Window Server access is set through the Preferences application. From a remote host, you can then launch an application and specify that the windows should appear on the target machine like this:

% /NextApps/Webster.app/Webster -NXHost TargetHost

In this case, Webster launches on the remote host and the windows show up on TargetHost. "TargetHost" must be the hostname; you cannot substitute an ip address.

It's not possible to use NXHost from a machine running Release 3 to a machine running an earlier release. However you can run an application on a Release 2 machine and have its windows display on a Release 3 machine. (In addition, you cannot use NXHost from a Release 1 machine to a Release 2 system, or vice versa.)

Q: How can I get my mouse pointer to stop jumping around, and to glide smoothly across the screen?

A: Type the following command into a shell window:

% dwrite NeXT1 MouseScaling "*string*"

Where "*string*" contains a single value indicating the number of integer pairs to follow, followed by the actual pairs. The integer pairs are (speed, acceleration) pairs. These integer pairs make the mouse movement on the screen dependent both on the distance the mouse was moved on the pad, and its acceleration and speed. When you change the mouse speed through the Preferences application, it creates one of these. Here's the format of a MouseScaling argument:

% dwrite NeXT1 MouseScaling "N x1 a1 x2 a2 x3 a3 x4 a4 ... xN aN"

To give the mouse a smoother motion across the screen, you must make the mouse movement linear (uniform, but slow). This **dwrite** will do the trick:

% dwrite NeXT1 MouseScaling "1 1 1"

This means that if you move the mouse x amount on the pad, it moves it by kx pixels on the screen regardless of how long it took. (k is the constant which translates the mouse pad coordinate system to the screen coordinate system.)

Warning: we cannot guarantee the support of **dwrite**s in future releases, so do not put this in your application or rely on it in any way.

Valid for 2.0, 3.0, 3.1

Q: Why won't the entry on the last line of of my **/etc/crontab** or **/etc/crontab.local** file not execute? I'm certain the syntax is correct (I can execute the same command from a shell).

A: You've probably used the Edit program to add the last line of **crontab** or **crontab.local**. The **cron** program is very sensitive to the format of these files. If there is not a newline character following the last line, **cron** will not execute the last line. The solution is to edit the file by placing the cursor after the last character and pressing the Return key. Note that **vi** does not exhibit this behavior (it automatically places a newline in the correct place).

Q:When I try to run **/usr/bin/calendar** with an argument, it returns the following error:

/tmp/calendar: syntax error at line 1: `^' unexpected

What's going on?

A:There is a bug in **/usr/bin/calendar** which causes the command **calendar -** to fail. **calendar -** is normally run via the **cron** utility; it examines each user's **~/calendar** file for things that will happen the next day, in order to send that user a reminder. **calendar** can be fixed with the following patch.

Line 20 of the file **/usr/bin/calendar** needs to be changed from:

```
( cat /etc/passwd; nidump passwd . ; /usr/lib/calendar -p ) | sort -t: -u +0 -1 |
```

to:

```
( cat /etc/passwd; nidump passwd . ) | sort -t: -u +0 -1 |
```

If you have network user accounts, change "nidump passwd ." to "nidump passwd /". This tells **calendar** to use the user list in the root NetInfo domain.

NeXTSTEP Boot and Driver Disk Images

These floppy images have been created as a convenience for those who may have a damaged install floppy, or who need to get crucial drivers onto a NEXTSTEP floppy but don't have a running NEXTSTEP machine.

If you have a damaged installation floppy, the only way to create a new one, even under NEXTSTEP, is to make a copy of another one. The instructions for creating floppies from images under NEXTSTEP are in the next section.

If you have a machine configuration which requires a certain driver (usually a SCSI adapter driver) which is not provided on the installation driver floppy, and you don't already have a running NEXTSTEP system, you need to create one under another system. If you have DOS running on your PC, you can download the proper driver floppy image and create a NEXTSTEP disk under DOS using the rawrite program.

This document only discusses floppy images for the NeXTSTEP operating system, versions 3.3 and earlier. If you need OPENSTEP version 4.x floppy images, see **Document 71921**.
This article has been archived and is no longer updated by Apple.

Creating NEXTSTEP Floppies From Images Under NEXTSTEP

1 Make sure you are logged in as **root**.

2 Download the floppy image and decompress it from the Workspace via the File->Uncompress menu item. Make sure you are logged in as root.

3 Insert a blank 1.44 megabyte 3.5" HD floppy disk into the floppy drive.

4 In the Workspace, choose the command Check For Disks from the Disk menu. Initialize the disk as a NEXTSTEP filesystem. NEXTSTEP then formats and initializes the disk. When it is done initializing, select Eject from the disk menu, but leave the floppy in the drive.

5 If you have placed the image in **/tmp**, type this command to copy the boot floppy image to the new disk.

 # dd if=/tmp/*Floppy_Image* of=/dev/rfd0b

6 After a few minutes, the duplication will be complete. Type this command:

 # disk -e /dev/rfd0b

7 Physically eject the disk from the drive. It is ready to use.

Creating NeXTSTEP Floppies Under DOS

1 Download **rawrite 2** from:

ftp://ftp.debian.org/debian/tools/rawrite2.zip

and copy it to your DOS system. If necessary, rename the file to rawrite.exe.

2 Download the floppy image that you need to your DOS system. Remember that DOS will not support the original NeXTSTEP filename.

3 Prepare a floppy by formatting it for DOS.

4 Run **rawrite**. It will ask you for the source file (the floppy image) and the destination drive.

5 When rawrite has completed, the floppy is ready to be used under NeXTSTEP.

For more information about **rawrite**, see the Readme at the end of this document.

3.2 Boot Floppy Image

Download the 3.2 Boot Floppy Image from:

http://download.info.apple.com/Apple_Support_Area/Apple_Software_Updates/MultiCountry/Enterprise/nextstep/floppyimages/3.2_Boot_Disk.floppyimage

This floppy image is an exact copy of the boot floppy that shipped with NEXTSTEP 3.2.

3.2 Additional Drivers Floppy Image

Download the 3.2 Additional Drivers Floppy Image from:

http://download.info.apple.com/Apple_Support_Area/Apple_Software_Updates/MultiCountry/Enterprise/nextstep/floppyimages/3.2_Addl_Drivers.floppyimage

It contains these drivers:
1520_Adaptec154xDriver.ReadMe.rtf
1626_DPT2000SCSIDriver.ReadMe.rtf
1670_PS2KbdMouseDriver.ReadMe.rtf
1676_Adaptec6x60SCSIDriver.ReadMe.rtf
1692_Adaptec2740Driver.ReadMe.rtf
1694_IDE8265Driver.ReadMe.rtf

3.2 Motorola Boot Floppy Image

Download the 3.2 Motorola Boot Floppy Image from:

http://download.info.apple.com/Apple_Support_Area/Apple_Software_Updates/MultiCountry/Enterprise/nextstep/floppyimages/3.2_Moto_Boot_Disk.floppyimage

This floppy image is an exact duplicate of the installation floppy that ships with NEXTSTEP 3.2 for Motorola.

3.3 Boot Floppy Image

Download the 3.3 Boot Floppy Image from:

http://download.info.apple.com/Apple_Support_Area/Apple_Software_Updates/MultiCountry/Enterprise/nextstep/floppyimages/3.3_Boot_Disk.floppyimage

This floppy image is an exact copy of the floppy that shipped with NEXTSTEP 3.3.

3.3 Driver Floppy Image

Download the 3.3 Driver Floppy Image from:

http://download.info.apple.com/Apple_Support_Area/Apple_Software_Updates/MultiCountry/Enterprise/nextstep/floppyimages/3.3_Driver_Disk.floppyimage

This floppy image is an exact copy of the driver floppy that shipped with NEXTSTEP 3.3.

3.3 PCCard Installation Floppy Image

Download the 3.3 PCCard Installation Floppy Image from:

http://download.info.apple.com/Apple_Support_Area/Apple_Software_Updates/MultiCountry/Enterprise/nextstep/floppyimages/3.3_PCCard_Install.floppyimage

This floppy image is provided as a convenience for installing NEXTSTEP using PCCard(PCMCIA) SCSI or network adapters. It should be used only in conjunction with the 3.3 Additional Drivers Floppy. For instructions on using these floppy images to perform PCCard installations, see NeXTanswer 1985_Installing_from_PCCard_Devices.rtf.

3.3 Core Drivers Floppy Image

Download the 3.3 Core Drivers Floppy Imagefrom:

http://download.info.apple.com/Apple_Support_Area/Apple_Software_Updates/MultiCountry/Enterprise/nextstep/floppyimages/3.3_Core_Drivers.floppyimage

It contains these drivers:
1784_EISABus_Driver_Overview.rtf
1785_Floppy_Driver_Overview.rtf
1790_Intel_824X0_PCI_Chipset_Driver_Overview.rtf
1799_PCI_Bus_Driver_Overview.rtf
1800_Intel_82365_and_compatible_PCMCIA_chipset_Driver_Overview.rtf
1801_PCMCIABus_Driver_Overview.rtf
1804_PS2Keyboard_Driver_Overview.rtf

This image contains the latest versions of the basic drivers needed during an install of NEXTSTEP. It should be used as the first Driver Floppy during an install.

The floppy driver is also on the NEXTSTEP CDROM, but may be needed in cases where you need to access the floppy while booted single-user off the CDROM. There is a link missing on the CDROM that is necessary for using driverLoader.

3.3 Additional Drivers Floppy Image

Download the 3.3 Additional Drivers Floppy Image from:

http://download.info.apple.com/Apple_Support_Area/Apple_Software_Updates/MultiCountry/Enterprise/nextstep/floppyimages/3.3_Addl_Drivers.floppyimage

1752_AMD_PC_SCSI_Driver_Overview.rtf
1754_SymbiosLogic53C8xxSCSIDriver_Driver_Overview.rtf
1759_Adaptec_274x_and_284x_family_Driver_Overview.rtf
1760_Adaptec_2940_family_and_7870_integrated_Driver_Overview.rtf
1761_Adaptec_6x60_chipset_add-on_and_integrated__Driver_Overview.rtf
1771_BusLogic_family_Driver_Overview.rtf
1830_DPT_SCSI_family_Driver_Overview.rtf
1839_EIDE_Driver_Overview.rtf

NOTE: This floppy image should be used with the 3.3 Core Drivers Floppy Image.

3.3 Motorola Boot Floppy Image

Download the 3.3 Motorola Boot Floppy Image from:

http://ftp.info.apple.com/Apple_Support_Area/Apple_Software_Updates/MultiCountry/Enterprise/nextstep/floppyimages/3.3_Moto_Boot_Disk.floppyimage

This floppy image is an exact duplicate of the installation floppy that ships with NEXTSTEP 3.3 for Motorola.

3.3 Beta Install Drivers Floppy Image

Download the 3.3 Beta Install Drivers Floppy Image from:

http://ftp.info.apple.com/Apple_Support_Area/Apple_Software_Updates/MultiCountry/Enterprise/nextstep/floppyimages/3.3_Beta_Drivers.floppyimage

This floppy contains drivers necessary for installing NEXTSTEP for Intel Processors. The drivers are still in Beta, so they are separated from the main Additional Drivers Floppy. It contains the Beta versions of these drivers:

1758_Adaptec_154x_family_and_compatible_Driver_Overview.rtf
1839_EIDE_Driver_Overview.rtf
2129_Bus_Logic_FlashPoint_Driver_Overview.rtf

Readme For rawrite.exe Program

RaWrite 1.3

Disclaimer of Warranty

Users of this software must accept this disclaimer of warranty: "This software is supplied AS IS. Mark Becker disclaims all warranties, expressed or implied, including, without limitation, the warranties of merchantability and of fitness for any purpose. Mark Becker assumes no liability for damages, direct or consequential, which may result from the use of this software."

Purpose

Write a disk image file to a floppy disk.

Equipment/Software Requirements
---

* PC/XT/AT or 100% compatible with at least 256K of RAM and a floppy disk drive.

* MS-DOS version 3.21 or greater.

* A formatted diskette.

This program uses well-documented generic low-level DOS and BIOS functions. It should run on nearly every PC in existance. PS/2's should be able to run RaWrite but this has not been tested.

CAVEAT

This program will write ANY disk file to a floppy, overwriting any previous information that may have been present. If you wish to re-use a diskette that has been written to by RaWrite then that diskette will probably need to be reformatted; all MS-DOS specific information will have been erased.

Usage

C> RAWRITE

And follow the prompts. All arguments are case-insensitive.

If the source and destination drives are the same, RaWrite will ask the user to swap diskettes as required. Rawrite allocates a large buffer in RAM to reduce the number of disk swaps.

RaWrite may be aborted at any time by typing ^C or CTRL-Break.

Errors

RaWrite attempts to determine if the diskette is a 1.44M, 1.2M, 720K, or 360K diskette by reading sectors 18, 15, and 9 in that order. If the inserted diskette is not one of the these types, then RaWrite will abort with an error message.

Errors such as write protect, door open, bad disk, bad sector, etc. cause a program abort with a short error message.

NeXTSTEP Text Programming Q&A

Disclaimer

This document pertains to the NeXTSTEP operating system, which is no longer a supported product of Apple Computer. This information is provided only as a convenience to our customers who have not yet upgraded their systems, and may not apply to OPENSTEP, WebObjects, or any other product of Apple Enterprise Software. Some questions in this Q&A document may not apply to version 3.3 or to any other specific version of NeXTSTEP.
This article has been archived and is no longer updated by Apple.

Questions

Q: When should I use **NXLocalString()** and when should I use **NXLocalizedString()** in my code? The localization chapter in /NextLibrary/Documentation/NextDev/Concepts just discusses **NXLocalizedString()**.

A: **NXLocalString()** is an old name, and you should use **NXLocalizedString()** instead. The name **NXLocalString()** is only there for compatibility.

Q: The program **genstrings** complains if **NXRunLocalizedAlertPanel()** contains a constant (like from a #define) instead of a string. This means that we may end up having "OK" defined multiple times in the string table, since most alert panels include an "OK" button. Should I avoid using **NXRunLocalizedAlertPanel()**?

A: **NXRunLocalizedAlertPanel()** will be obsolete in the future, and we strongly recommend that you use **NXRunAlertPanel()** instead. It's true that **genstrings** doesn't eliminate duplicate entries from **NXRunLocalizedAlertPanel()**.

Q: The localization chapter in /NextLibrary/Documentation/NextDev/Concepts suggests using #define to retrieve a string just once. It seems like if we want to avoid extra lookups, we should define a variable, initialize it once to the result of an **NXLocalizedString()**, and then use it where necessary.

A: You are right. If you want to avoid extra lookups, you should define a variable to have the value. For example, you could do the following:

```
const char *fooString = NULL;
#define FOO_STRING (fooString = fooString ? fooString :
NXLocalizedString("Foo", NULL, "Nonsense."))
```

That way, the string will only be looked up if it is needed and will only be looked up at most once. The macro is a convenient way to make sure that the string has been initialized each time you want to use it, especially if you want to use it as an argument.

Q: How big a performance hit do I take for a lookup from a string table? At what size is it worth breaking up a string table into multiple files?

A: Lookups are cheap. It's only worth going to multiple files if you have hundreds of entries, or if you have a large number of entries which are almost never accessed or which are only accessed together such as error conditions or strings for a certain panel like an Inspector Panel.

Q: How can I determine which TextField is being edited, while performing a delegate

method such as textWillEnd: or textDidChange:?

A: All of TextField's delegate methods send the Text object as an argument. You can message this Text object to get *its* delegate, which has been set to the id of the TextField being edited. If you have several TextFields in a Matrix (or a Form) then the Matrix (or the Form) is the delegate of the Text object. In which case you should use the following method calls to get the actual TextField:

```
[[sender delegate] selectedCell];
```

This code also works for individual TextFields, because single Controls return self when asked for selectedCell. We recommend that you use the above code snippet in all cases.

Q: In my application I have overridden the Text object methods:

```
readRichText:atPosition:
writeRichText:forRun:atPosition:emitDefaultRichText.
```

However, no matter what I try, these methods are never called. I have also tried implementing the equivalent delegate methods:

```
textWillReadRichText:stream:atPosition:
textWillWriteRichText:stream:forRun:atPosition:emitDefaultRichText:
```

but I'm not getting anywhere here either. What am I doing wrong?

A: While these methods were implemented under 1.0, they have been obsoleted by replaceSelWithCell: and its associated methods in subsequent releases. Although these methods appear in the header file and the specification sheet for the Text object, they are never called within your application.

Q: How do the Text object margins work?

A: The margins do work, but it's difficult to correctly set them. You need to offset the values by the frame rectangle of the text. The following code snippet illustrates the necessary steps:

```
/* This routine assumes that you have defined currentDocText somewhere else */

#define DESIREDleftMARGIN some int value
#define DESIREDrightMARGIN some int value
#define DESIREDtopMARGIN some int value
#define DESIREDbottomMARGIN some int value

- setMargins:sender
{
NXRect aRect;

/* Get the current frame values */
[currentDocText getFrame:&aRect];
[currentDocText setMarginLeft: NX_X(&aRect) + DESIREDleftMARGIN
right: - NX_X(&aRect) + DESIREDrightMARGIN
top: NX_Y(&aRect) + DESIREDtopMARGIN
bottom: - NX_Y(&aRect) + DESIREDbottomMARGIN]; ];
return self;
}
```

If you call getMarginLeft:right:top:bottom:, the returned values are the same as the ones you provide to setMarginLeft:right:top:bottom:. So, to determine the "true" margins, you need to subtract the frame's dimensions.

Q: How do I get at the list of runs in a Text object, without subclassing the Text class? Once I have them, how do I determine how many of them there are?

A:

```
#import <appkit/Text.h>

@interface Text(Private)
- (int)nRuns;
@end

@implementation Text(Private)
-(int)nRuns
{
return theRuns->chunk.used/sizeof(NXRun);
}
@end

main ()
{
id text = [[Text alloc]
initFrame:NULL text:"Hello there" \\
alignment:NX_LEFTALIGNED];
printf("there are %d runs.\\n", [text nRuns]);
}
```

Q: I'm trying to use the pasteFont: method of the Text object to extract font information from the Font Pasteboard. The trouble is, when I try to do this, I always get the default font information<Helvetica 12pt. What am I doing wrong?

A: The solution is easy but perhaps not obvious. In order for the paste operation to have any effect, the Text object must contain a selection. It is not even strictly necessary that it contain any text. The following code illustrates the ªlow-painº method of extracting font values from the Pasteboard. (The alternative ªhigh-painº method would involve parsing the rich text format from the Pasteboard):

```
#import <appkit/Text.h>
#import <appkit/Font.h>

id font, myText;

/* Allocate a temporary Text object */
myText = [[Text alloc] init];

/* It must allow multiple fonts -- i.e. rich text */
[myText setMonoFont: NO];

/* Stick in some text -- optional */
[myText setText:"hello"];
```

```
/* And select it -- any selection will do so long */
/* as something is selected */
[myText setSel:0 :1];

/* pasteFont: will copy the font info from the Pasteboard
/* to the font in the Text object */
[myText pasteFont:sender];

/* Do what you need to with the font */
font = [myText font];

/* Then free up the Text object */
[myText free];
```

Q: How can you add text to the end of a text object?

A: The trick is to make a zero length selection at the end of the text, and add the new text there. The following code snippet illustrates the necessary steps:

```
/* This routine assumes that you have defined currentDocWindow somewhere else */

- addText:(const char *)newString
{
int length;
id currentDocText;

/* Get the current text document */
currentDocText = [[currentDocWindow contentView]docView];
length = [currentDocText textLength];
[currentDocText setSel:length :length];
[currentDocText replaceSel:newString];

return self;
}
```

Q: How do I append text to a text object, such that the new text makes use of a different font?

A: First of all, make sure that the text object can contain multiple fonts. Send the following message to your text object:

```
id myText;
...
[myText setMonoFont:NO];
...
```

Then, use the following code snippet to append the text, select the text, and change its font:

```
id myText;
int length;

...
length = [myText textLength];
[myText setSel:length:length]; // put an empty selection at the end of the text
[myText replaceSel:"some new text"]; // add some text
[myText setSel:length :[myText textLength]]; // select the newly added text
[myText setSelFont:[Font newFont:"Symbol" size:24.0]]; // change its font
...
```

The above code works in all releases and leaves the text selected.

The following code snippet **will not work** (in Release 1.0 or 2.0) due to the way in which setSelFont:, and replaceSel: interact. (For 3.0 this code snippet works similar to the code above except that the text is not highlighted when completed.)

```
id myText;
int length;

...
length = [myText textLength];
[myText setSel:length:length]; // put an empty selection at the end of the text
[myText setSelFont:[Font newFont:"Symbol" size:24.0]]; // change the font
[myText replaceSel:"some new text"]; // add some text
...
```

For 2.0:
To avoid some of the flashing that may occur to the text object while selecting and modifying the font programmatically, you should perform a **disableDisplay** on the window containing the text object before selecting and modifying the text. After the modifications you should then **reenableDisplay** on the window and **display** the text object.

Q: Why won't my textField become firstResponder? The following code is in my **appDidInit:** method:

```
[[NXApp mainWindow] makeKeyAndOrderFront:self];
[[NXApp mainWindow] makeFirstResponder:myTextField];
```

The I-beam cursor does not appear in myTextField. In the debugger, **makeFirstResponder:** returns the id of the window as it should. And when asked, the window claims that the textField *is* the firstResponder. What's going on?

A: The problem is that **makeFirstResponder:** just sets the firstResponder. It does not modify the selection. You have to explicitly set the selection if you want the cursor to appear in the TextField. The method **selectText:** does the trick<and it calls **makeFirstResponder:** for you. Try using the following code instead:

```
[[NXApp mainWindow] makeKeyAndOrderFront:self];
[myTextField selectText:nil];
```

The same is true of Form objects as well. For Forms you must do the following:

```
[[NXApp mainWindow] makeKeyAndOrderFront:self];
[myForm selectTextAt:0];
```

Q: I am trying to set the background color for my TextField. It seems that the color is being ignored. What is going on? Here is my code, which uses a color well:

```
- setBackgroundColorWithWell:sender
{
[myTextField setBackgroundColor:[sender color]];
[myTextField display];
return self;
}
```

A: You must set shades in both the color model and the gray model separately. The AppKit figures out what type of machine is being used and sets the window depth for the window accordingly.

The model of being able to specify colors and gray separately can be useful; typically you don't want to give a TextField some random color when it is displayed in a monochrome window. For instance, yellow 12 point text on a red background is usually reduced a few pixels when displayed in a 2-bit window. Thus, in most cases you might want a TextField to remain black on white on the monochrome display. Or you might want to just alter the foreground while always keeping the background white. If you do want the gray and color values to track, then you have to set them both, as shown below.

```
- setBackgroundColorWithWell:sender
{
[myTextField setBackgroundColor:[sender color]];
[myTextField setBackgroundGray: NXGrayComponent([sender color])];
[myTextField display];
return self;
}
```

Q: When I use the Action Cell method setAlignment: in conjunction with the Cell method setScrollable:, I experience some inconsistent behavior. If I have called [myTextCell setAlignment:NX_CENTERED] and [myTextCell setScrollable:YES], the display does not update in the cell. However, when the TextFieldCell is sent [myTextCell setScrollable:NO], then the display works fine.

A: The Text Object does not support scrolling for centered or right-justified text. To get proper display, you have to disable scrolling with [myTextCell setScrollable:NO] when using the method setAlignment: with the values NX_CENTERED or NX_RIGHTALIGNED. If your text is left-justified, scrolling will work fine, i.e. you can use[myTextCell setAlignment:NX_LEFTALIGNED] with [myTextCell setScrollable:YES].

OPENSTEP 4.2 for Mach Patch 1 Overview

This patch is now obsolete. Please see the OPENSTEP Current Patch List, **TIL article 70033**, for information on the most current patches for OPENSTEP and Enterprise Objects Framework. This obsolete patch is provided here as a convenience to our customers who have not yet upgraded to the most current patch level.
This article has been archived and is no longer updated by Apple.

About This Patch

This OPENSTEP 4.2 for MachOS patch fixed several problems relating to date processing including a number of problems with processing dates after 1999. This patch is obsolete; please see the OPENSTEP Current Patch List, **TIL article 70033**, for information on the most current patches for OPENSTEP and Enterprise Objects Framework

Installing OPENSTEP 4.2 for Mach Patch 1

1. **Download** the Mach version of the patch from Apple's FTP site at ftp.info.apple.com. The file is located at:

```
/Apple_Support_Area/Apple_Software_Updates/MultiCountry/Enterprise/openstep/patches/4.2Mach_Patch1.pkg.compressed
```

2. Uncompress the Mach package file. Your web browser or FTP client may perform this step for you.

3. Log in as root. If you're not sure how to log in as root, see your system administrator.

4. Double-click on the 4.2_Mach_Patch1.pkg file. Make sure that no OPENSTEP applications are running before you perform this step.

5. Click the Install button in the Installer package window. An Install Package panel will open.

6. Click 'Install' in the Install Package panel and, when prompted for confirmation, **click OK** to proceed. The Installer window displays information about the progress of the installation, which may take several minutes.

Problems Fixed

Corrected in OPENSTEP 4.2 for Mach Patch 1

Four Digit Year Entry with /bin/date
Apple reference # : 2179467

PROBLEM:
Certain dates could not be input using the Unix /bin/date command which shipped with OPENSTEP 4.2.

RESOLUTION:
The /bin/date command now correctly handles 2-, 3-, and 4-digit years for dates in the valid Unix range (1 Jan 1970 - 31 Dec 2037). This patch allows four-digit year entry through /bin/date. In addition, input dates are now checked for validity and out-of-range dates are rejected.

New RCS Package
Apple reference # : 2249097

PROBLEM:
The version of RCS which shipped with OPENSTEP 4.2 did not handle dates after 1999 correctly in some commands.

RESOLUTION:
This patch installs RCS version 5.7, a much more recent version which does not experience this date problem. Please see the RCS documentation for a complete list of new and updated features in this release.

Hardware Clock Setting
Apple reference # : 2253935, 2258123

PROBLEM:
Previously, setting a date after 1999 with /bin/date or with the OPENSTEP Preferences application would cause an illegal value to be stored in the hardware clock of Intel and NeXT-branded Motorola hardware systems. As a result, some systems would show an incorrect year after reboot.

RESOLUTION:
With this patch, the hardware clock is now set correctly for dates after 1999.

Date handling in ftpd

Apple reference # : 2251927

PROBLEM:
The ftp daemon's MDTM command did not handle dates after 1999 correctly.

RESOLUTION:
The ftp daemon has been updated to handle these dates correctly.

tmac Macro Date Handling
Apple reference # : 2256331

PROBLEM:
Previously, default dates generated by the tmac macros used for troff and nroff typesetting were not correct for years after 1999.

RESOLUTION:
The various man, me, and ms macros now generate default dates after 1999 correctly.

Date reporting in atq
Apple reference # : 2258151

PROBLEM:
In OPENSTEP 4.2, the atq command displayed the job date incorrectly for jobs created with the at command after 1999.

RESOLUTION:
The atq command has been modified to correctly represent jobs scheduled from 1970 through 2037.

Job scheduling and execution with at and atrun
Apple reference # : 2263271

PROBLEM:
Under certain circumstances, atrun did not correctly handle jobs scheduled with at after 1999.

RESOLUTION:
The at and atrun commands have been modified to correctly and consistently handle the scheduling and execution of jobs regardless of date.

Date display in /usr/ucb/mail
Apple reference # : 2259253

PROBLEM:
In OPENSTEP 4.2, the Date: header of email messages written by /usr/lib/sendmail used a two-digit year in the creation time. This problem affected email created and read with the /bin/mail and /usr/ucb/mail programs.

RESOLUTION:
sendmail has been modified to write four-digit years in the date header.

ntpd Error Messaging
Apple reference # : 2260775

PROBLEM:
Under OPENSTEP 4.2, the error message returned when an excessive offset was encountered did not report the year correctly for years after 1999.

RESOLUTION:
This error message now reports the year correctly.

MacRecorder Driver 1.0: Incompatible with Macintosh Portable

I'm trying to use Farallon's MacRecorder with my Macintosh Portable running System Software 6.0.7. The files SoundEdit and HyperSound are working fine.

When I place the MacRecorder Driver in the System Folder and restart, the driver doesn't load (the icon appears with an 'X' through it).

This article has been archived and is no longer updated by Apple.
The MacRecorder Driver 1.0 is not compatible with the Macintosh Portable. Version 1.0.2 is the latest version as of July 1992 and it is compatible with the Macintosh Portable and System 6.0.7.

Farallon has sold the MacRecorder software and hardware to MacroMedia (formerly MacroMind) and they're responsible for supporting the product now.

To locate a vendor's address and phone numbers, use the vendor name as a search string.

Macintosh SE/30: Problems with Ethernet Caused by ADEV

My Macintosh SE/30 is freezing up when I use it as a server and router (using an AppleTalk Internet Router and a Kinetics Ethernet card). Could it be that the 68030 Direct Slot card is interfering with the processor in some way?

This article has been archived and is no longer updated by Apple.
We are not aware of any problems using the Macintosh SE/30 in the configuration you describe. The Macintosh SE/30-AppleShare-Router combination is freezing probably because of a problem with the Ethernet card's ADEV. We suggest you try reinstalling the ADEV and see if that solves the problem.

Macintosh: Where Changes Are Stored When a File Is Edited

For security reasons, I need to know where changes stored during editing of a document. Is there a temporary document created, or are the changes stored in RAM until I save or exit the document?

This article has been archived and is no longer updated by Apple.
How a document stores changes varies depending on the manufacturer. For instance, MacPaint is a "RAM based" program and keeps its "changes" in the application heap space. MacPaint saves changes to disk only when you choose Save, whereas Microsoft Word buffers data to the disk.

Generally, if your program is creating "temp" files, it is writing changes to disk. For instance, with MultiFinder running, launch Microsoft Word and note how it creates a Word Temp file in the System folder. Quit Microsoft Word (saving your document using Save or Save As) and the "Word Temp" file disappears. Not all temp files are visible, and some applications may buffer data to disk without being so obvious.

If you must know if an application buffers user data to disk, ask the manufacturer of your software.

A related issue is the Virtual INIT and Virtual in System 7. By design, both programs buffer data to disk (but you have the option to turn them off).

Solana H Server: Problems with Large Phase 2 Networks

Is there a problem using Solana H-Servers on large multiple-zone AppleTalk Phase 2 networks?

This article has been archived and is no longer updated by Apple.

There is a problem maintaining router tables on very large networks.

Occasionally, several routers can get their battery-backed RAM blown, though they still stay running from 30 minutes to several hours, depending on network traffic. When the routers finally start to go down, you'll begin to see erroneous, duplicated, and scrambled zone names and device names. Then all the routers will stop completely and begin flashing their error indicators.

You can restart the routers, but their routing tables will be scrambled. Each time you try restarting the problem only gets worse. Completely resetting PRAM only temporarily fixes the problem.

Solana has discontinued business to our knowledge, so we are unable to refer you to them directly for further information.

System 7: Workaround for 32-bit Incompatible Boards

Article Change History

08/21/92 - REVIEWED
* For technical accuracy; edited.

If a computer is set to 32-bit mode under System 7 and has a 32-bit incompatible board installed, you get an error chime at startup and a sad Macintosh on the screen, or both. How do you fix the problem?

This article has been archived and is no longer updated by Apple.

To fix this, do the following:

* Remove the incompatible board or boards.

* If you still have your video card installed (assuming it's not the incompatible card), start up from a 6.0.x floppy and you will get a dialog prompting you to change to 24-bit addressing.

- OR -

* If you don't have your video card, start up from your System 7 and reset the Parameter RAM by holding down Command-Option-p-r at start up.

These procedures will reset the addressing to 24-bit mode.

System 7.x: How to Prepare a Network Install Folder

Can the System 7.x Installer that is shipped on a floppy disk or CD ROM do a network install?
This article has been archived and is no longer updated by Apple.
Yes. There is only one version of the Installer and it can be setup to perform a network installation. This same process works for all versions of System 7.

This is how you do it:

1. Create a folder called Net Install on a shared volume.

2. Drag all disk images needed for the installation (all disks except the Disk Tools disk) to the Net Install folder. A folder will be created inside the Net Install folder that corresponds to each diskette.

3. Drag the Installer and the Install script from the Install Me First or Install 1 diskette to the top level of the Net Install folder.

4. The Net Install folder is now prepared for remote users to use for performing system software installations. Once they log into the remote volume, they double click the Installer icon and the installation process will run.

System 7: Unmounting a Disk

How can I unmount a disk (floppy, server, or hard disk) and remove the disk image from the desktop, besides dragging it to the Trash? System 6.0.5 and System 6.0.7 eject a disk and remove its icon from the desktop when I press Option-Command-E.

This does not appear to work with System 7.0. All System 7.0 seems to support is Command-E, so you still have to drag an icon into the trash.

This article has been archived and is no longer updated by Apple.
Command-Option-E does not work in System 7.0. Command-Y has taken over that function.

Select the disk icon and either choose Put Away from the File menu, or use the keyboard equivalent, Command-Y.

Mac OS: Hiding an Application When Switching to Another

Can I switch to another running application and hide the current application in one step?
This article has been archived and is no longer updated by Apple.
Yes you can. While holding down the Option key, select the application you want to switch to by selecting the application from the Application menu. You can also click in any open window of the application you wish to switch to.

Having the Option key held down hides the current application, including any windows open in the Finder, and makes the application you selected active.

This feature is possible with any version of the Mac OS beginning with Mac OS 7.0.

MacTerminal, versions earlier than 2.0: Backspacing

This article has been archived and is no longer updated by Apple.
The host you communicate with using MacTerminal may or may not support the methods of backspacing available to you on the Macintosh. To determine whether the host does recognize methods of backspacing used by the Macintosh, try typing CTRL-H to delete a character, or hit the backspace key (upper right corner of the keyboard) to reposition the cursor without deleting the character. If neither method works, you'll need to consult the host's operating manual.

NOTE: In version 2.0, the backspace and delete keys can be swapped.

TA45951_ThirdParty_Video_Cards_for_the_Macintosh_Family_(TIL07282).pdf

Third-Party Video Cards for the Macintosh Family

Do you know of any third-party video cards that work with the Macintosh Classic, Macintosh LC, and Macintosh IIsi?

This article has been archived and is no longer updated by Apple.
Lapis Technology manufactures a line of video interface cards, called the DisplayServer series, for the Macintosh family, including the Macintosh Classic, Macintosh LC, and Macintosh IIsi.

RasterOps Corporation also makes a line of video cards for the Macintosh family, including the Macintosh Classic, Macintosh LC, and Macintosh IIsi.

These cards support both Apple and third-party monitors.

To locate a vendor's address and phone numbers, use the vendor name as a search string.

System 7: Correction to Installer Message on Macintosh Plus

This is a notice about an incorrect message given by the System 7 Installer on a Macintosh Plus.

This article has been archived and is no longer updated by Apple.
If customers attempt to install System 7 to floppy disks and choose "Minimal Installation for Macintosh Plus," the Installer screen INCORRECTLY reads as follows:

"This package contains the minimal set of system software for use on the Macintosh Plus. It is intended to create a high-density (FDHD) startup disk that will only be used with the Macintosh Plus."

This statement is incorrect. Aside from the hard drive requirement, users cannot install System 7 to high density floppy disks on a Macintosh Plus because there are no SuperDrives (FDHD 1.44MB) for the Macintosh Plus. The 1.44MB floppy drives are not supported by the Macintosh Plus ROMs.

Refer to the System 7 Installation manual, which states the hardware requirements--including a hard drive--to install System 7.

System 7: Installing EtherTalk Phase 1 under System 7

Article Change History

08/24/92 - REVISED
* To include information from two other articles.

Are networks running AppleTalk Phase 1 still supported under System 7?

If so, how do I install AppleTalk Phase 1 for Ethernet under System 7?
Where is the Phase 1 resource we are to use?

This article has been archived and is no longer updated by Apple.

System 7 automatically installs and supports AppleTalk Phase 2 networking software. If your network consists entirely of LocalTalk, PhoneNet, or TokenTalk (or some combination thereof), this has absolutely no impact on you and you don't need to read any further. Phase 2 software only affects networks that have EtherTalk.

But a Phase 1 EtherTalk driver that works with System 7 is available on the CD that comes as part of the System 7 Group Upgrade Kit. The procedure and software for installing Phase 1 under System 7 are contained on the CD, or on AppleLink.

The reason for this approach is that Apple is migrating the installed base to AppleTalk Phase 2. We want all new System 7 users to automatically have Phase 2 software on their Macintosh computers. However, some people will be installing System 7 on their existing Phase 1 networks, and they will need the Phase 1 EtherTalk driver until they have completed their migration to Phase 2.

The datalink software (EtherTalk and TokenTalk) included and installed with System 7 is Phase 2. However, a network of mixed Phase 1 and Phase 2 drivers can be implemented, provided the network administrator has set up the internet routers with the appropriate migration utility. Migration issues will affect only those networks using EtherTalk datalink software, because no version of TokenTalk predates version 2.0.

Network applications (like AppleShare File Server and Print Server software), system software, and its associated services are Phase independent. They can connect to and use services on any AppleTalk network.

The following is the Read Me file that is found on the Group Upgrade Kit CD:

EtherTalk Phase 1

EtherTalk¿ software allows communication with AppleTalk¿ network services over Ethernet networking interface cards and media. EtherTalk Phase 2 software is part of Macintosh¿ system software version 7.0. This folder contains an earlier version of EtherTalk software, EtherTalk Phase 1.

You only need to install EtherTalk Phase 1 software for users who have Ethernet networking interface hardware and who are connected to a network that has not been upgraded to support AppleTalk Phase 2. AppleTalk Phase 2 transition and upgrade are discussed in the "System 7 Group Upgrade Guide."

To install the EtherTalk Phase 1 software, begin by installing the

EtherTalk software as part of the System 7 installation procedure. Next, drag the EtherTalk icon to the icon of your System Folder (not the open System Folder window). It is automatically placed in the Extensions folder inside the System Folder.

To select the EtherTalk Phase 1 software, open the Control Panels folder, located in the System Folder. Double-click the Network control panel. Finally, select the EtherTalk icon.

A/UX: Sendmail and Domain Name Server (8/94)

How do I get "sendmail" to work under A/UX?

This article has been archived and is no longer updated by Apple.
The version of "sendmail" in A/UX requires your local network to be running with Domain Name Server (DNS), which is /etc/named. The README file in /usr/lib/sendmail.conf directory describes in more detail the type of mailers currently supported.

Choose one of the machines on your network as a primary Domain Name Server
to prevent any host name conflicts. (See the "Setting Up Network Mail" section in the "A/UX Network System Administration" manual on how to do this.)

The distributed sendmail.cf file included with A/UX doesn't work on every network.

After you have a Domain Name Server configured and running properly on the network, execute these commands to get sendmail working:

CD /usr/lib
kill -9 the-running-sendmail-process-id
mv sendmail.cf sendmail.cf.orig
mv sendmail.cf.NEW sendmail.cf
rm -f sendmail.fc # remove the old sendmail frozen file
sendmail -bz # create a new sendmail frozen file
/usr/lib/sendmail -bd -q30m # restart the sendmail

To get all the domain names resolved with the domain name server machine, create a file called /etc/resolv.conf on the machines not running /etc/named.

Here is an example of the content of /etc/resolv.conf:

domain support.apple.com
nameserver 130.43.4.9

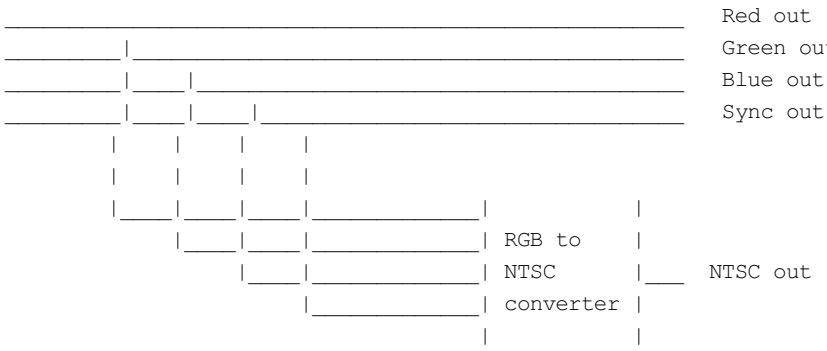
Macintosh: How To Get Simultaneous RGB and NTSC Output

I'm trying to setup my Macintosh so it can simultaneously output an NTSC video signal for cable TV and an RGB signal for an Electrohome projector.

I've been able to do this by tapping the RGB signal from the Macintosh and feeding into a scan converter, but this creates a lot of interrupts on the projector.

I've been looking at NTSC boards, like the one from TrueVision, but these boards don't support simultaneous RGB output. What I need is a single board that outputs both signals.

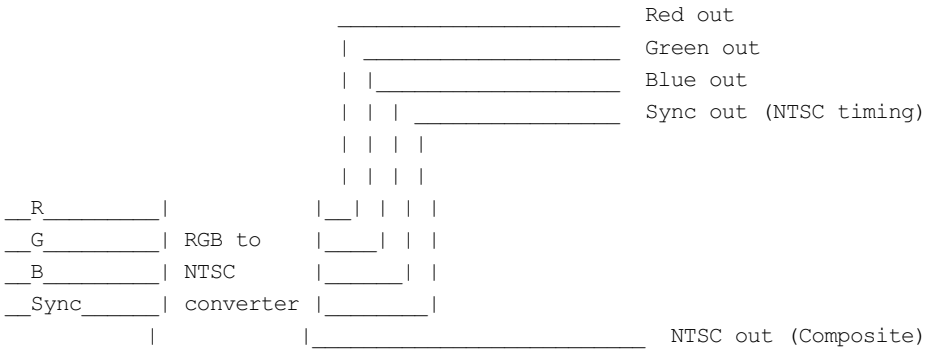
Here's what I've been doing:



This article has been archived and is no longer updated by Apple.
We doubt there is one video card available that provides simultaneous Macintosh-style RGB (synchronization rate of around 31K) and NTSC signals (synchronization rate of around 15K).

However, if your Electrohome projector is a multi-sync RGB monitor that has NTSC sync timing, there are several options available. You can use a TrueVision NuVista card and have its RGB signal timed to the NTSC sync signal. Both the RGB signal and the composite signal are timed to the 15K sync of the NTSC specification. If your Electrohome projector has the ability to sync to NTSC timing, the Macintosh video output can go to the Electrohome as RGB and as composite NTSC for TV devices.

Here's the schematic:



The converters discussed below use this approach to drive both a RGB device and a NTSC device with the same video image simultaneously.

There are several cards that will work. The key is that the video card must be able to produce the NTSC sync timing to drive the converter.

* The NuVista+ (newer) or NuVista (older) with VIDI/O Box

* Several RasterOps video cards with their Video Expander Box

* The Macintosh Display Card 4*8, Macintosh Display Card 8*24, and Macintosh Display Card 8*24 GC with either the VIDI/O or Video Expander

* Any cards listed as compatible with VIDI/O or Video Expander

RGB devices used in this situation must be able to sync to the 15K NTSC timing produced by the video cards.

The TrueVision card has a variety of NuVista+ cables for connecting different products, including BNC, S-Video, composite (RCA style), and so on. The NuVista+ video card is like the VIDI/O Box on the Macintosh NuBus card: the card doesn't need a separate converter box.

Cables for the VIDI/O Box and the Video Expander Box use standard RCA style connectors for composite NTSC, standard S-Video connectors for the S-Video NTSC, and individual BNC connectors for the NTSC RGB. Depending on what you need, standard off-the-shelf cables may work, or you may need to create custom cables.

LocalTalk PC Card: LAP Driver (11/94)

Is there a driver for the old LocalTalk PC Card now called the PhoneNetTalk PC Card from Farallon that will give my software raw LAP packets? I don't want a DDP interface like ATALK.SYS. The Clarkson packet driver, "localtlk", doesn't do what I want because it has a packet interface that uses ATALK.SYS and gives IP packets. What I need are raw LAP packets.

This article has been archived and is no longer updated by Apple.
We haven't seen a driver that has LAP level packets, but there is a source of information available that may help. The APDA document, "LocalTalk PC Card and Driver Preliminary Notes" (APDA part number M7055), describes how to write low-level software to control and communicate with the card. The note contains sample code in C and detailed information about programming.

For specifics on other cards, you'll need to contact the manufacturer. We suggest you contact DayStar Digital, Inc. on the LT200, and Sun Select (formerly Sitka Corp.) about the FlashCard. Also contact Farallon for information on the PhoneNetTalk PC Card.

Applesoft Internals: Using Applesoft ROM Subroutines (2 of 2)

The following notes, first published in The Apple Orchard (March 1980) are written for experienced 6502 machine language programmers who wish to use the Applesoft ROM subroutines. The addresses given are for an Apple II+ with an Applesoft firmware card, or Applesoft loaded into a Language Card.

Consult your Applesoft Reference manual for more information.
This article has been archived and is no longer updated by Apple.

Miscellaneous Routines

PTRGET DFE3
Read a variable name from CHRGET and find it in memory. On entry TXTPTR points to the first character of the variable name. On exit the address to the value of the variable is in VARPNT and Y,A. If PTRGET can't find a simple variable it creates one. If it can't find an array it creates one dimensioned from 0 to 10 and sets all elements equal to zero.

GETARYPT F7D9
Read a variable name from CHRGET and find it in memory. On entry TXTPTR points to the first character of the variable name. This routine leaves LOWTR pointing to the name of the variable array. If the array can't be found the result is an OUT OF DATA ERROR.

FNDLIN D61A
Searches the program for the line whose number is in LINNUM.
On exit:
C set LOWTR points to the link field of the desired line.
C clear then not found. LOWTR points to the next higher line.

DATA D995
Move TXTPTR to the end of the statement. Looks for the ":" or eol (0).

DATAN D9A3
Calculate the offset in Y from TXTPTR to the next ":" or eol (0).

REMN D9A6
Calculate the offset in Y from TXTPTR to the next eol (0).

ADDON D998
Add Y to TXTPTR.

SCRTCH D64B
The "NEW" command. Clears the program, variables, and stack.

CLEARC D66C
The "CLEAR" command. Clears the variables and stack.

STKINI D683
Clears the stack.

RESTOR D849
Sets the DATA pointer, DATPTR, to the beginning of the program.

STXTPT D697
Set TXTPTR to the beginning of the program.

BLTU D393
Block transfer makes room by moving everything forward.
On entry:
Y,A and HIGHDS = destination of high address + 1
LOWTR = lowest address to be moved
HIGHTR = highest address to be moved + 1

On exit:
LOWTR is unchanged
HIGHTR = LOWTR - $100
HIGHDS = lowest address transfered - $100

REASON D3E3
Makes sure there's enough room in memory for another variable. Checks to be sure that the address Y,A is less than FRETOP. May cause garbage collection. Causes "OUT OF MEMORY ERROR" if there's no room.

GARBAG E484
Move all currently used strings up in memory as far as possible. This maximizes the free memory area for more strings or numeric variables.

CONT D898
Moves OLDTXT and OLDLIN into TXTPTR and CURLIN.

NEWSTT D7D2
Execute a new statement. On entry TXTPTR points to the ":" preceding the statement or the zero at the end of the previous line. Use NEWSTT to restart the program with CONT. THIS ROUTINE DOES NOT RETURN.

RUN D566
Run the program in memory. THIS ROUTINE DOES NOT RETURN.

GOTO D93E
Uses LINGET and FNDLIN to update TXTPTR. GOTO assumes that the 6502 registers and A have been set up by the CHRGET that fetched the first digit.

LET DA46
Uses CHRGET to get address of the variable, "=", evaluate the formula, and store it. On entry TXTPTR points to the first character of the variable name.

High resolution graphics routines

NOTE: Regardless of which screen is being displayed, HPAG (location $E6) determines onto which screen the software draws graphics. ($20 for HGR, $40 for HGR2)

HGR2 F3D8
Initialize and clear page 2 High-Res.

HGR F3E2
Initialize and clear page 1 High-Res.

HCLR F3F2
Clear the current High-Res screen to black.

BKGND F3F6
Clear the current High-Res screen to last plotted color.

HPOSN F411
Positions the High-Res cursor without plotting. HPAG determines which page the cursor is pointed at.
On entry:
Horizontal = Y,X
Vertical = A

HPLOT F457
Call HPOSN then try to plot a dot at the High-Res cursor's position. The dot may not be plotted if plotting non-white at a complementary color X coordinate.

HLIN F53A
Draws a line from the last plotted point or line destination to the coordinate in the 6502 registers.
On entry:
Horizontal = X,A
Vertical = Y

HFIND F5CB
Convert the High-Res cursor's position to X-Y coordinates. HFIND allows the user to tell where on the screen the a shape table left the cursor.
On exit:
$E0 = horizontal lsb
$E1 = horizontal msb
$E2 = vertical

DRAW F601
Draw the shape pointed to by Y,X using the current HCOLOR starting at the current High-Res cursor position. On entry A = rotation factor.

XDRAW F65D
Draw the shape pointed to by Y,X by starting at the current High-Res cursor position inverting the existing color of the dots the shape draws over. On entry A = rotation factor.

SETHCOL F6EC
Set the High-Res color to X. X must be less than 8.

SHLOAD F775
Loads a shape table into memory from tape above MEMSIZ (HIMEM) and sets the pointer at $E8.

Error Processor Routines

ERROR D412
Checks ERRFLG and jumps to HNDLERR if ONERR is active. Otherwise it prints <cr> "?" <error message pointed to by X> "ERROR". If this is during program execution then it also prints" IN " and the CURLIN.

HANDLERR F2E9
Saves CURLIN in ERRLIN, TXTPTR in ERRPOS, X in ERRNUM, and REMSTK in ERRSTK. X contains the error code. See the Applesoft Reference Manual page 136 for the value of X for a given error.

RESUME F317
Restores CURLIN from ERRLIN and TXTPTR from ERRPOS and transfers ERRSTK into the 6502 stack pointer.

ISCNTC D858
Checks the Apple keyboard for a CTRL-C ($83). Executes the BREAK routine if there is a CTRL-C.

CHKNUM DD6A
Make sure FAC is numeric. See CHKVAL.

CHKSTR DD6C
Make sure FAC is a string. See CHKVAL.

CHKVAL DD6D
Takes the result of the most recent FAC operation and check this result for a string or numeric variable. A TYPE MISMATCH ERROR results if FAC and C don't agree.
On entry:
C set checks for strings
C clear checks for numerics.

ERRDIR E306
Causes ILLEGAL DIRECT ERROR if the program isn't running. X is modified.

ISLETC E07D
Checks A for an ASCII letter ("A" to "Z"). On exit C set if A is a letter.

PARCHK DEB2
Checks for "(", evaluates a formula, and checks for ")". Uses CHKOPN and FRMEVL then falls into CHKCLS.

CHKCLS DEB8
Checks at TXTPTR for ")". Uses SYNCHR.

CHKOPN DEBB
Checks at TXTPTR for "(". Uses SYNCHR.

CHKCOM DEBE
Checks at TXTPTR for ",". Uses SYNCHR.

SYNCHR DECO
Checks at TXTPTR for the character in A. TXTPTR is not modified. Normally exits through CHRGET. Exits with SYNTAX ERROR if they don't match.

Lisa 7/7: Form feeds during printing

This article has been archived and is no longer updated by Apple.

If the Lisa 7/7 document you wish to print is less than 1/2" from the top of the page, the Lisa will send a form feed to the printer and begin printing the document on the next page of paper. This feature replaces the dialog box in version 2.0 stating that "the paper is about to be rolled back, lift the bail...". We made this change so that Lisa 7/7 software would be able to support queued printing, which should be able to run unattended.

Macintosh Portable: RAM Upgrade Card Issues

1) Can I use a PDS Memory Card with a third-party RAM Slot memory card? The information available in the TIL suggests that the Apple Memory Card should be removed if a PDS Memory Card is in use. If third-party cards will work, which ones do you recommend? Can you be more specific regarding the problem with the memory decode chip?

2) The Pseudo Static RAM cards are not compatible with older versions of the Macintosh Portable. Is this because of different pinouts on the new logic board or because of Pseudo Static RAM?

3) With an upgraded Macintosh Portable, will both the RAM slot and PDS memory cards work? Will Pseudo Static memory work in the upgraded system?

4) What is the maximum amount of RAM that is supported in the Macintosh Portable's RAM slot?

This article has been archived and is no longer updated by Apple.

1) PDS memory cards are compatible with third-party RAM Slot memory cards. PDS cards do not use the Apple Memory Decode Chip, so there are no compatibility problems. Any third-party card designed for the new Macintosh Portable should work. Contact the card's manufacturer for compatibility information before buying.

The only memory card affected by the memory decode chip problem is Apple's. When an Apple 1MB or 3MB PSRAM Memory Board is installed, you cannot use the PDS for RAM expansion. The Apple card will try to decode memory accesses above the 4MB boundary.

2) The pseudo static RAM of the upgraded Macintosh Portable requires a refresh line. SRAM cards designed for the original Macintosh Portable will not work with the new Macintosh Portable.

3) The Backlit Upgrade consists of a new bezel (including display) and a card that goes into the ROM slot that powers the backlit display. PDS cards and RAM from the original system will work in the upgraded system.

4) For the new Macintosh Portable, the RAM slot can support up to 3MB of PSRAM, with 1MB soldered on to the main logic board. The PDS card can support up to 7MB of RAM (provided the Apple Memory Card is not used) making for a grand total of 8MB for the system.

Macintosh Processor Upgrade Card: Read Me

This article contains the Read Me file for the Macintosh Processor Upgrade Card.

This article has been archived and is no longer updated by Apple.

Important Information About Your Macintosh Processor Upgrade Card

Congratulations on purchasing a Macintosh Processor Upgrade Card. The information in this document adds to and updates the information in your Macintosh Processor Upgrade Card User's Guide and the manuals that came with your computer. Read the tips below as well as your manuals to take full advantage of the increased speed and new capabilities your computer will have after you install the Macintosh Processor Upgrade Card.

Using the Processor Upgrade Card

Once you turn on the Processor Upgrade Card, the 601 Processor Upgrade Enabler file must remain on your hard disk (it is installed on your hard disk with the upgrade card software). This file is also on the Install Me First and the Disk Tools disks that came with the upgrade card, and you can start the computer with either of those disks. If your computer will not start up, follow the instructions on reinstalling system software in the Macintosh Processor Upgrade Card User's Guide.

To turn the Processor Upgrade Card on and off, choose Control Panels from the Apple menu and double-click the 601 Processor Upgrade control panel icon to open it. Click Off to turn the card off and use the 040 processor that originally came with your Macintosh. Click On to turn the card on and use the 601 (PowerPC) processor. You must restart your computer for the change to take effect.

Memory requirements for animation

When the Processor Upgrade card is turned on, you may experience problems when watching computer animation. Increasing the amount of memory assigned to the program may help. To increase the program's memory, click the program's icon (in the Finder) to select it, and choose Get Info from the File menu. Type a bigger number in the Preferred size box.

You can also try running the animation with the card turned off, or installing more memory (RAM).

Using CloseView and the Apple Video Player

If you have a Macintosh LC630 or Quadra 630 with a Video In or TV Tuner card installed: CloseView does not work with the Apple Video Player program. To view video or TV with Apple Video Player, turn off CloseView with the CloseView control panel or by typing Command-Option-O.

Using CPU Energy Saver

If you have a Macintosh LC575: CPU Energy Saver is not compatible with the Macintosh LC575. CPU Energy Saver is located in the Apple Extras folder. Do not install this file into your System Folder because it may cause your computer to function improperly.

Using Custom Install to install the upgrade card software

Apple recommends that you use Easy Install to install the upgrade card software. If you choose Custom Install instead, some items may be installed that are incompatible with the upgrade card. Two such items are described below.

Assistant Toolbox Extension: If you have problems printing to the LaserWriter Select 310 with the Macintosh Processor Upgrade Card turned on, check for a file called Assistant Toolbox Extension in your Extensions folder (in the System Folder).Throw away this file and restart your Macintosh, then try printing again.

AutoRemounter: If you notice slower performance over a network, check in the Control Panels folder for a file named AutoRemounter. Throw away this file and restart your Macintosh.

Mention of third-party products is for informational purposes only and constitutes neither an endorsement nor a recommendation. Apple assumes no responsibility with regard to the performance or use of these products.

Final Cut Pro 1.0: Using Color in the Text Tool

I am using the Titling feature and would like to have each letter in the same word a different color. I am unable to do this. Are there any workarounds?
This article has been archived and is no longer updated by Apple.
The text tool, defined as an effects generator, uses global parameters.

One parameter is allowed for each element. An element can be a word, sentence, or even a letter. Several elements (letters) can be formed together as a word to produce a multi-color word. Using multiple elements to form a word also allows the use of Key Frames to change characteristics over time. With this feature, one can create such eye-catching effects as movement, orientation, perspective, and more.

Final Cut Pro also supports Photoshop layers, which can be "flown" around a path to create motion - adding extra dynamics to a scene. In this scenario, the letters of a word could be broken up among several layers in Photoshop, then imported into Final Cut Pro to be animated.

Final Cut Pro includes the FX Builder. Using this powerful scripting tool, effects can be modified or written that support any number of parameter adjustments.

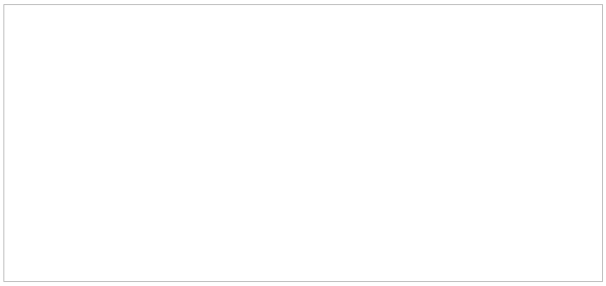
Sherlock: Error When "All Search Sites" Selected

When I perform a search of the Internet, using Sherlock with all "Search Sites" enabled, I encounter difficulties.
This article has been archived and is no longer updated by Apple.
Sometimes while attempting to use Sherlock to search the Internet after turning all search sites On, your Macintosh may freeze, or you may encounter this error message:



This is probably a case of Sherlock's memory partition being too small, as the default is set at 1,024k (1 MB).

The default memory partition should be adequate for the default search sites, but if you need to search a lot of sites and expect to get many hits (300-plus), increase the memory partition in Sherlock to 2 MB by following these steps:

- Inside the System Folder, find the Apple Menu Items folder.
- Locate the Sherlock icon and select it.
- Choose Get Info from the File menu.
- Use the Show: dropdown menu to select Memory.
- In the Memory Requirements section, enter 2048 (kBytes, or 2 MB) in the Preferred Size: box.
- Close Sherlock's Info using the close box in the upper-left corner.

Mac OS X Server 1.2: Quicktime Streaming Server Remote Admin Capabilities

How can I view current status and administer a QuickTime Streaming Server remotely?
This article has been archived and is no longer updated by Apple.
Note: Any reference in this article to Mac OS X Server pertains to version 1.2, which was released prior to May 2001.

You can display the QTSS server status and stats via HTTP by following these steps:

1. In NetInfoManager, locate the settings for QuickTime Streaming Server.
2. Locate the property named:

web_stats_url:

3. Give this property a value such as "privatestats" (or whatever you prefer).
4. Stop and restart the QuickTime Streaming Server.

This enables real-time status and stats to be viewed via HTTP. From a web browser (such as Microsoft Internet Explorer or Netscape Navigator), use the following URL to access this information:

```
http://yourserver.ip.com:554/privatestats
```

(substitute the IP or DNS name for "yourserver.ip.com")

To administer the QuickTime Streaming Server remotely, you can use "niutil" from a telnet session as root. For example, use the following command to replace steps 1-3, above:

niutil -createprop . /services/QuickTimeStreamingServer
web_stats_url privatestats

(this is one-long line, press [RETURN] at the end of "privatestats")

For further information on niutil, consult the man pages via the command 'man niutil'

MacX: Default Color Map Is Macintosh System Palette

Article Change History

04/21/93 - UPDATED
* To include MacX 1.2 information.

When trying to plot a color bar of 256 colors, MacX shows me a full range of colors on the left side of my screen (colors 0 through 128, or so), but shows only a solid color on the right (colors 128 to 256). When printing to a Tektronix color printer, the screen dump routine returns a mirror message "130 colors found". This occurs in both rooted and rootless windows.

The color bar is complete (256 colors) on both the screen and printer when running White Pine's Exodus II and matches the color table of the host.

Why isn't MacX displaying all the colors?

This article has been archived and is no longer updated by Apple.
There are many X client applications that use the standard or default X color map. MacX uses the standard Macintosh System palette as the default color map (which it should), though this can lead to the situation you describe. The System palette has 128 colors locked in and no additional colors specified.

If you, using the X client application, request a new color map from MacX, you should get all 256 colors.

In MacX 1.2 loading the standard color map is an option in the display preferences dialog.

AppleShare: A/UX Users Take About Two Minutes to Disconnect

On a network with many workstations running A/UX, I log in to our AppleShare server, do some work, and log off. The window on the server indicates that I'm still logged in. This problem doesn't happen with identical workstation running under Macintosh System 6.0.7.

This article has been archived and is no longer updated by Apple.

This problem happens under both A/UX 2.0 and 2.0.1. User's names are not IMMEDIATELY disconnected from the Connection User List in AppleShare, but they will disappear after about two minutes from log off of an A/UX workstation.

MacX: Using with Motorola X Clients

Article Change History

04/20/93 - REVIEWED
* For technical accuracy.

I'm trying to have session using MacX 1.1 and MacTCP Tool 1.1 with a:
* Motorola 8640
* UNIX SVR3.2
* X11R3

My MacX application opens fine, but when I try to execute any X sessions, I get the error message:

The remote command "xclock" could not be executed using the tool "MacTCP Tool". Creation of the remote stream failed. The connection came up halfway then failed."

?sers can create a X session on the Motorola box and send it to the MacX screen via the 'setenv' command. However, the session executed and sent to the Macintosh doesn't fit on a less than 19-inch Macintosh monitor.

What configurations does the Motorola box need:
* via /usr/etc/n.rexecd?
* via /etc/hosts.equiv?

Are there compatibility issues running a MacX X11R4 server against an X11R3 client?

This article has been archived and is no longer updated by Apple.
This scenario sounds familiar. Your problem is most likely with the remote host, the "rexecd" service not functioning properly, or some restriction while executing the "rexecd" command.

We knew this was happening on some of Sun's systems. Sun implemented a "feature" in their "rexecd" code that doesn't allow a host (that isn't listed in the /etc/hosts file) to execute the "rexecd" command. The solution is to add the Macintosh IP address and host name to the Sun's /etc/hosts file.

If /etc/hosts file is not the issue, check to see if the "rexecd" service is available. Usually, the Internet Server database is kept in the /etc/servers file, in A/UX for example, an entry would look something like this:
exec TCP /usr/etc/in.rexecd

and the official Internet Service name database is kept in the /etc/services file, an entry in A/UX for example looks something like:

exec 512/TCP

The "rexecd" daemon uses a TCP protocol and listens on port number 512.

Regarding the Macintosh monitor problem, what was the X client's "geometry" specification on the command line? This display problem can happen if the "geometry" is specified to be larger than the display size of the MacX. If no "geometry" is specified, the default geometry is taken from the

application. Try to specify the "geometry" within the size of the MacX display.

We don't think there is a compatibility issue for a MacX 11R4 server running against an X11R3 client.

AppleShare PC: 7.0 LaserWriter Driver Not Required

Do AppleShare PC users need to use the 7.0 LaserWriter driver? Is this a question that should be addressed to Farallon?

This article has been archived and is no longer updated by Apple.
AppleShare PC has no need for the 7.0 LaserWriter driver or its prep information (also called Laser Prep, md, or Macintosh Dictionary).

When AppleShare PC prints to a LaserWriter, it uses one of two methods, depending on how it's connected. If it's set up for Epson LQ-2500 emulation, an emulation dictionary downloads with each job. This doesn't interfere with md (if it is present) and is purged at the end of the job.

If AppleShare PC is set up for PostScript printing, no dictionaries download at all. Only data made by the MS-DOS application are used. These data pass directly to the LaserWriter without changes. These data can cause problems depending on the application's print driver requirements. We haven't yet done any testing yet but don't expect any compatibility problems.

Personal LaserWriter NT: "setprintername" Character Restrictions

Using a Personal LaserWriter NT, I am trying to change the network name and type of the printer. To do this, I'm using the PostScript code:

```
-----
%!
serverdict begin 0 exitserver
statusdict begin
(Print Station:CuccaPS) setprintername
end
-----
```

This code works fine for the LaserWriter Plus and LaserWriter IINT, but not the Personal LaserWriter NT. Can the Personal LaserWriter NT change its network type?

This article has been archived and is no longer updated by Apple.
The PostScript setprintername operator was not designed for changing the LaserWriter's type. The operator should not allow any of these characters as valid string components:

: @ * = ┼

While these characters may not always cause errors on older LaserWriters, they do cause unusual behavior with the Personal LaserWriter NT. They are invalid characters because they are field separators and wildcards, as defined by the AppleTalk Name Binding Protocol (NBP).

The format of an NBP entity name (such as a LaserWriter's Printer Access Protocol server) is:

object:type@zone or Etch A Sketch:LaserWriter@Bandley3

If the ":" character were part of a LaserWriter's name, software attempting to address the LaserWriter would become confused and not know where the object's name leaves off or the type begins.

With the Personal LaserWriter NT, the setprintername operator is only able to change the object name. This forces the entire string into the object entry. Because the ":" character is invalid, the product operator must be used to obtain a valid AppleTalk name.

The LaserWriter Namer utility (shipped with each LaserWriter) prevents users from defining names with invalid characters. But not all PostScript interpreters enforce this restriction properly.

Published Date: Feb 18, 2012

Hayes InterBridge: Limits

It appears that my Hayes InterBridges can't handle lots of zones with long zone names. The InterBridges only process one packet per reply for zone information. People on the other side of the Hayes InterBridges can see only 150 zones out of 183.

This article has been archived and is no longer updated by Apple.

The 150 zone limit you've discovered is a characteristic of Hayes Phase 1 InterBridges.

	Phase 1	Phase 2
Maximum number of zones	150	250
Maximum number of networks	300	500
Current ROM version of InterBridge	1.12	2.10

Long zone names are not a problem with Hayes InterBridges as they will support zone names of any length.

A/UX 2.0: Toolbox Shutdown Manager Routines Correction

Using A/UX 2.0, I want to run a self-written program as a stand-alone application without the Finder. When I change the "mac32" startup script to "/mac/bin/startup -f ApplicationName &" things work fine except for the logout. Because the 'ExitToShell' procedure doesn't do a logout, I tried using the Shutdown Manager routines.

The "A/UX Toolbox: Macintosh ROM Interface" documentation mentions that the A/UX Toolbox routines 'ShutDwnPower' and 'ShutDwnStart' do an exit to the user's login shell. I've tried using both routines, but they work just like normal Macintosh Toolbox routines (in other word, they shutdown and restart the machine).

This article has been archived and is no longer updated by Apple.

First of all, one minor correction: /mac/bin/startup SHOULD BE either /mac/bin/startmac or /mac/bin/startmac24

The "ShutDwnPower" and "ShutDwnStart" routines documented in the "A/UX Toolbox: Macintosh ROM Interface" are WRONG! The routines behave the same as Mac OS Shutdown Manager routines (shutdown and restart).

To Logout from user's login shell, use the AUXDispatch() trap with the A/UX_LOGOUT selector. All definitions for the AUXDispatch trap are specified in the header file /usr/include/mac/aux.h.

For more detailed information about AUXDispatch trap, please refer to page 3-15 on "A/UX Toolbox: Macintosh ROM Interface" documentation.

SuperPaint: How To Use with 32-Bit QuickDraw

Can SuperPaint 2.0 work with 32-Bit QuickDraw?

This article has been archived and is no longer updated by Apple.
Follow these steps when using SuperPaint 2.0 with 32-bit QuickDraw:

1) Before launching SuperPaint, Go to the Monitors CDEV.

2) Set to four colors or grays.

3) Close the CDEV.

4) Launch SuperPaint.

5) Select the Preferences menu.

6) Turn on the preference "Use QuickDraw only for screen rendering".

7) Quit SuperPaint.

8) Go to the Monitors CDEV.

9) Set to the preferred color/gray level.

Published Date: Feb 18, 2012

DECnet: Tunneling and Network Traffic

Using PATHWORKS and DECnet tunnels, I am trying to set up a 23-location WAN. I have a star and a central VAX at the home office. I'm going to use existing 9.6Kb DECnet links because I expect to do night time downloads only.

1) What would the RTMP traffic look like over the DECnet links assuming I have around five routers in the home office? Do the half routers on each VAX exchange routing table information?

2) Is there internal tunnel maintenance traffic outside of the standard AppleTalk traffic?

3) Anything else to look at?

This article has been archived and is no longer updated by Apple.

1) With DECnet Tunneling, each VAX on each side of the tunnel is an AppleTalk half-router for routing AppleTalk traffic over DECnet. Since AppleTalk for VMS version 3.0 is a full implementation of AppleTalk Phase 2 protocol stack on VAX/VMS, the RTMP traffic will be similar to any other AppleTalk network. And because half-routers are logically a full router, they periodically broadcast and receive RTMP Data packets to and from all other routers on its directly connected networks, backbones, or the DECnet links.

2) Within the Tunnel traffic, there should not be any other traffic besides the standard AppleTalk traffic. The Tunnel is made up of DECnet logical links, so it needs all the DECnet maintenance traffic (such as circuit hello and listen traffic) to be maintained.

3) With AppleTalk for VMS 3.0, we strongly recommend that your wide-area link is at least 56KB or higher. Though you don't expect a high traffic load, we are not clear on how you will do the night time download. If your network has any delay longer than two minutes, you might have problems with AppleShare. If the ASP session timer of two minutes expires, the session terminates and you lose the server connection.

Another problem may be with NBP lookup. Users might not see the file server when opening the Chooser and selecting the AppleShare icon. Some sites have to change a resource, called GNRL, to increase the Chooser interval timer and retry timer values. You can find a complete description of these two problems in the Tech Info Library on AppleLink. Search using keywords "AppleTalk and Wide and Area".

The other thing to look into is the capability of the central VAX since it serves as a single-point hub to the other 23 nodes. Does it have enough power to provide satisfactory performance?

Since you already have DECnet links, we suggest bringing up one tunnel at a time and stress test it with typical file download. Keep adding tunnels to see if performance remains acceptable. You might find that, at some point, you will want to add resources to the central VAX and/or increase the speed of the communications link.

Macintosh System 6.0.x: Don‘t Begin File Name with Period

Using System Software 6.0.7, I create a file and name it ".temp". If I select the file and try to duplicate it with the Finder "Duplicate File" command, it won't. The screen blinks then comes back. If I keep trying to duplicate the file, the Finder bombs.

This article has been archived and is no longer updated by Apple.
Apple is aware of this problem, which has to do with a patch to the "Open" trap for the Slot Manager. The Slot Manager assumes that all attempts to open a file that has a period ('.') as the first character in its name is a driver for a NuBus card.

This will always be a problem with System Software 6.0.x-based Macintosh systems. There are no workarounds that we are aware of except not using a period as the first character in a file name.

System Software 7.0 has a call that prevents this problem from happening. The call that causes the problem is "FSOpen". The new call is "OpenDF" and will be documented in Inside Macintosh Volume VI. The difference between the two calls is that FSOpen can open both files and devices; OpenDF can only open files.

This problem will still happen in System 7.0 if the old call is used. This will be the case with all existing applications and possibly new applications for System 7.0 specifically. Both calls will work under System 7.0. We recommend that developers use the new calls for their System 7.0 applications.

DAL: MVS Server Questions

I have a few questions about DAL for MVS specifically relating to the MVS/TSO DAL Server:

1) What is the overhead of DAL on the Host, both disk blocks (space) and memory while running?

2) In what form or where does the Server run on the IBM Host?

3) How does DAL deal with security packages such as ACF2?

4) I'm using EDS Net to navigate through the network to the host. How do I configure a DAL application, such as one of the Query packages, to navigate through the EDS network parameters?
This article has been archived and is no longer updated by Apple.
1) To install and use DAL, you need:

* Any release of MVS that supports DB2 Version Release 3 or higher

* 52 tracks of available space on a 3380

* TSO logins with at least 2048K of memory

* Either the DB2 DSNLOAD library allocated to native TSO or these modules copied to the load library containing the DAL load modules:

* DSNACAB
* DSNACAF
* DSNALI
* DSNHLI2
* DSN3ID00.

* Appropriate hardware and software for the supported network connection.

Keep in mind that large database queries can create temporary datasets on disk, but they are erased after the query is complete.

2) DAL will run in the users TSO address space. Each user needs a TSO id.

3) We have a number of customers using DAL that have ACF2 on their systems and they coexist without any problems. ACF2 has to be set up to support the RACROUTE call. This call is standard so it is likely that the customer's ACF2 is already set up to support it.

4) We don't know how to configure DAL to work within these parameters. If EDS Net doesn't support Macintosh-to-host using one of the connections listed below, DAL probably won't work in that environment:

* Apple Coax/Twinax Card connection using Apple MacDFT.
* Apple TokenTalk Card NB connection using Apple MacDFT
* Apple Serial NB Card connection using Apple MacDFT.
* Netway 1000/2000 connection.
* Avatar MacMainFrame connection.
* DCA MacIrma connection.
* SNA*ps 3270 Gateway connection.
* Asynchronous dial-in to a protocol converter (as long as the protocol converter accepts VT100 terminal type input).

Published Date: Feb 18, 2012

DAL: How It Checks Communication Lines for Errors

I'm using a Macintosh DAL client to have sessions with a DAL server running on a VAX (asynchronous) and an IBM 3090 with a 3270 card. Does DAL implement an error free data link on top of the communications channel so that glitches in the data flow do not effect the results of a query?

This article has been archived and is no longer updated by Apple.

Data Access Language does not add error checking on top of the transport data link. That would produce unnecessary overhead. Instead, DAL uses the error checking provided by the transport methods. On asynchronous lines, it can specify parity, databits, stop bits, flow control, packet length, modem timeout, and dial attempts.

For AppleTalk connections, DAL relies on ADSP to handle errors, and for 3270 connections, DAL uses the 3270 display station protocol (LU2) or the APPC (LU6.2) protocol.

MacX: "Bad STARTFONT" Statement Error Caused by Lower Case Type

Article Change History

04/20/93 - REVIEWED
* For technical accuracy.

I cannot seem to get MacX 1.0.1 to compile BDF fonts properly. MacX keeps converting the fonts into 0 byte files and complains about a "Bad STARTFONT statement".

This article has been archived and is no longer updated by Apple.
We tried compiling one of the sample BDF files under MacX 1.0.1 without any problems. The first line in the BDF file must be ALL UPPER CASE, such as "STARTFONT 2.1". Otherwise, you will get the "Bad STARTFONT statement" message.

Published Date: Feb 18, 2012

A/UX: Correction to "A/UX Programming Language and Tools" Manual

I've noticed an error in the A/UX Programming Language and Tools, Vol. 2, chapter 25, page 5, section 13. The sample doesn't work at all, and there is a bug in the first and third line.

For example, try this source code (test.c):

```
char *_Version_ =
"(c) Copyright 1986\\
Standard Software Version V.2.1";
main
{
printf ("hello world\\n");
}
```

compile it with: cc test.c
then get the version number with : version a.out
but no version number is available

Who can explain to me how to correctly use the 'version' utility, that is, how to create a string variable to be used by version utility?

This article has been archived and is no longer updated by Apple.
First of all, the example in the "A/UX Programming Language and Tools. Vol. 2, Chapter 25, Section 13, page 5" is INCORRECT. The same is also true for volume one of the manual.

The version program attempted to look for a string of the following form:

{Apple version RELEASE.LEVEL YY/MM/DD HH:MM:SS}

where the capitalized words(RELEASE, LEVEL, YY, MM, DD, HH, MM, SS) are matched by numbers. Both RELEASE and LEVEL numbers can be up to 8 digits in length, the rest (YY, MM, DD, HH, MM, and SS) must be EXACTLY 2 digits. Both "{" and "}" symbols, and "Apple version" words are also required to match. Only one SPACE is allowed before words RELEASE, YY, and HH.

If the defined character string for version does not meet any of the above matching criteria, the 'version' program will display "no version number found".

The above character string, for example, should be changed to:

```
char *_Version_ =
"(c) Copyright 1986\\
{Apple version 2.1 86/09/12 18:05:24}";
```

This has been fixed in the A/UX 3.0 documentation.

A/UX: Using A/UX as a Print Spooler (8/94)

I'm running A/UX on an Macintosh IIfx. I'm using "lpr" to print to a LocalTalk LaserWriter. I also have HP/Apollo workstations on the same Ethernet. I want to print to the LaserWriter from the HP. My file goes to the A/UX spool folder, but needs to be printed by A/UX. How do I print directly to the LaserWriter from another IP node?

This article has been archived and is no longer updated by Apple.
For the HP (or any other IP node) to print to a LaserWriter connected to the A/UX box, you have to edit the /etc/printcap file of the remote system to reflect the A/UX system. It should have an entry like this:

```
remote:\\
:lp=:\\
:rm=a/ux.hostname:\\
:rp=lp:\\
:sd=/usr/spool/remote:
```

The above entry brakes down as:

Line 1: Name by which the HP calls the A/UX system's printer

Line 2: Local printer designation

Line 3: Remote host name. This must also be in the host config file (/etc/hosts or equiv)

Line 4: Name of printer on the A/UX system. By default, this will be lp for a Chooser selected printer.

Line 5: Spool directory. This is a directory where remote print jobs will be spooled. Instructions on how to set this up follow.

To create the spool directory, do this:

```
(1) mkdir /usr/spool/remote
chmod 755 /usr/spool/remote
chgrp daemon /usr/spool/remote
chown daemon /usr/spool/remote
CD /usr/spool/remote
mknod pipe p
chmod 660 pipe
```

(2) Next, verify the /etc/hosts file on the HP that contains an entry which allows access to the A/UX system. It should look like:

```
134.66.20.45 aux_hostname aux_hostname.domain.com
```

The first entry is the IP address of the A/UX system. The second entry is the hostname of the A/UX system, and the final entry is the hostname and domainname of the A/UX system (optional if domain name servers are not being used).

(3) Finally, you must tell the A/UX system that it can accept print requests from the HP system. To do so, edit the /etc/hosts file on the A/UX system so that there is an entry for the HP. The format will be as shown above.

Next, add the HP's hostname to the /etc/hosts.lpd file on the A/UX system. If the A/UX box has not yet been set up for remote printing access, the /etc/hosts.lpd file will not yet exist. Create it and enter the HP hostname.

Now to invoke remote printing on the LaserWriter from the HP, use the lpr command as follows:

```
lpr -Premote filename_to_be_printed
```

Also, the newly created pipe in /usr/spool/remote MUST be owned and grouped by "daemon", otherwise, it won't be opened by the spooler.

```
chown daemon pipe; chgrp daemon pipe
```

TA45991_Apple_II_Family_Driver_Not_Yet_Available_for_LaserWriter_SC_(TIL07322).pdf

Apple II Family: Driver Not Yet Available for LaserWriter SC

I want to connect my Apple IIe to the Personal LaserWriter SC. Are there printer drivers to do this?

This article has been archived and is no longer updated by Apple.
There is no Apple support for connecting either the older LaserWriter IISC nor the new Personal LaserWriter SC to any Apple II computer. Apple has made low-level driver information available to developers to create such a driver, but we don't know of any available drivers as of April 1991.

Published Date: Feb 18, 2012

Apple PC 5.25 Drive: Compatibility with Macintosh Computers

Which Macintosh computers support the Apple PC 5.25 Drive?

This article has been archived and is no longer updated by Apple.
The Apple PC 5.25 drive is supported only by the Macintosh SE and the Macintosh II, systems that were introduced without the Apple SuperDrive (formerly Apple FDHD).

Later versions of Macintosh computers have the Apple SuperDrive, which supports 3.5-inch MS-DOS diskettes--eliminating the need for the Apple PC 5.25 drive.

For customers who need to use 5.25-inch MS-DOS diskettes, we suggest looking at third-party products, such as those made by Dayna Communications.

To locate a vendor's address and phone numbers, use the vendor name as a search string.

AppleTalk: 32 Device Limit Refers to Physical Connections

Is the AppleTalk 32 device limit referring only to physical connections (such as printers, computers, and so on) or is it the total number of logical and physical devices (such as TOPS, FileMaker, etc)?

This article has been archived and is no longer updated by Apple.

The limit of 32 devices is for physical hardware devices such as printers, computers, and so on.

Published Date: Feb 18, 2012

ImageWriter LQ: When Top Margin Increases with Each Page

I'm manually feeding a multi-page document through my ImageWriter LQ. The margins in Page Setup are set correctly at 1 inch, top and bottom. The paper size is correctly set to Letter, 8 1/2 x 11 inches.

The first page comes out fine, but all the other sheets' top margin increases by 1/2 inch.

This article has been archived and is no longer updated by Apple.
This problem is usually caused by the Manual Feed option not being selected in the Print dialog box. The printer assumes that it should not do a backfeed, and increases the top margin on each page. (Also be sure that the DIP switch 2-8 is set to Open.)

There is something else you might try: Select the Macintosh Print dialog box by holding down the Shift key while selecting Print from the File Menu. This allows you to use the Macintosh print drivers. When you select print without holding down the Shift key, you are accessing the application's print driver.

Synchronous and Asynchronous Communication Defined

What is asynchronous communication and how is it different from synchronous communication?

This article has been archived and is no longer updated by Apple.

Synchronous transmission means both the sending and receiving devices are on the same frequency. This method uses precise timing for error checking.

Asynchronous transmission sends each byte of data with a start bit at the front and a stop bit at the end. Timing is variable and is not used for error checking. Asynchronous transmission is a less sophisticated way to send data, but less complex and less expensive.

Macintosh System Software: Use Installer, Don‘t Drag-Copy

Is it really necessary to use the Installer application to put a new System on a Macintosh? What's wrong with just dragging over a good System Folder from another computer?

This article has been archived and is no longer updated by Apple.

Drag copying System Folders is not an acceptable method of replacing System files. You must use the Installer to get a complete and successful installation of all necessary visible and invisible System files. There are hooks and patches to the ROM that can be part of the System only if the Installer is used.

If you have a System that was installed by drag-copying, we suggest that you trash it and install a fresh System Folder using the Installer program.

Macintosh Plus: Allow 30 Seconds for SCSI Devices to Start Up

I have four SCSI hard disks daisy chained to a Macintosh Plus. On startup, only some of the hard disks mount, though they all mount when hooked up individually.

I've removed all internal terminators and replaced them with external ones, disabled all INITs, and checked the SCSI device numbers, all to no avail.

This article has been archived and is no longer updated by Apple.
This is a problem cause by the relatively slow speed of Macintosh Plus computers with old-style ROMs. All SCSI devices must be in the ready state before the computer or they won't be recognized. Be sure to wait around 30 seconds after turning on your hard drives before turning on the Macintosh Plus. You also might consider upgrading your Macintosh Plus' ROM.

Also, just for the sake of consistency, standardize on one brand/type of SCSI terminator.

Published Date: Feb 18, 2012

Apple II Family: No Support for Macintosh Hard Disk 20

Is it possible to use a Macintosh Hard Disk 20 with any Apple II computer?

This article has been archived and is no longer updated by Apple.
No, there is no support for the serial Macintosh Hard Disk 20 on any of the Apple II computers. A controller card was never produced to provide this compatibility.

Published Date: Feb 18, 2012

Apple IIGS: Compatibility with Macintosh Hard Drives

Can any Macintosh SCSI external hard drive work with the Apple IIGS?

This article has been archived and is no longer updated by Apple.
If the hard drive is advertised for compatibility with the Apple IIGS (which almost all currently available hard drives are) you should have no problem using it with an Apple IIGS.

Published Date: Feb 18, 2012

LaserWriter: Page Count Cannot be Reset

Is there any way to reset the page counter on a LaserWriter I/O board? I received one that did not show zero pages and it is going into a new engine.

This article has been archived and is no longer updated by Apple.

The page count number is intended to be a permanent record showing the number of pages processed by a particular print engine. The page count is comparable to the odometer in a car showing the distance travelled.

In an effort to prevent misuse, Adobe Systems withheld the publishing of any methods for resetting the page count on PostScript printers using their code. Although there are legitimate reasons for resetting the page count, Adobe and Apple will not publish this information.

In order to properly track the page count for maintenance purposes, it is recommended that you place a sticker inside the printer which notes the date and the page count when the printer was serviced. This will help ensure that the ozone filter and other consumable items are replaced at the recommended intervals.

Published Date: Feb 18, 2012

Personal LaserWriter NT: Can‘t Support 5MB of RAM

Can the Personal LaserWriter NT support 5MB RAM or must it jump from 2MB to 8MB?

This article has been archived and is no longer updated by Apple.

The Personal LaserWriter NT only supports 2MB or 8MB because its two SIMM slots are treated as one contiguous, single slot.

Published Date: Feb 18, 2012

LaserWriter II: Minimum Paper Length is 6 Inches

I'm trying to manually feed 8.5 x 5.5-inch paper into a LaserWriter IINTX. I keep getting the jam alarm as the paper reaches the fuser. (The paper is not actually jammed but the electronic sensor thinks it is.) Is my paper too short?

This article has been archived and is no longer updated by Apple.
The minimum paper length for the LaserWriter II engine is very close to 5.5 inches. At 5.5 inches, the paper has already left the feed rollers in the transfer guide assembly and may not be suitably fed into the fuser assembly. As the fuser cannot pick up the paper, a jam alarm goes off. Our measurements suggest that six inches is the minimum length for printer paper.

LisaProject 3.0: Copying and Pasting the Task Table

This article has been archived and is no longer updated by Apple.

When copying and pasting the Task Table into documents such as LisaCalc and LisaList, the late finish dates (4th column) is pasted over the top of the early finish dates (2nd column). Since you cannot select and Copy just a portion of the Task Table, you will have to correct the early finish dates manually.

Published Date: Feb 18, 2012

Macintosh Plus: Why There‘s No External Monitor Option

Why didn't Apple offer an external full-screen monitor option for the Macintosh Plus?

This article has been archived and is no longer updated by Apple.
The main reason is that the Macintosh Plus was not designed to support any expansion cards. Short of modifying the case, there was no supportable way to connect a driver board and cabling to the logic board of the Mac Plus. Additional load on the power supply would also be a concern.

Published Date: Feb 18, 2012

Macintosh Portable: Internal Hard Drive Can‘t Be Transferred

Is it possible to use the Macintosh Portable's internal hard drive in another Macintosh?

This article has been archived and is no longer updated by Apple.

No, it's not possible to mount the Macintosh Portable's hard drive in another member of the Macintosh family because it has a unique mounting bracket.

Published Date: Feb 18, 2012

LaserWriter: Turning It Off versus Leaving It On

Is it better to leave my LaserWriter on all the time or to turn it off when it's not in use?
This article has been archived and is no longer updated by Apple.
Generally speaking, any circuit will last longer if it is not continually turned on and off. Switching the power decreases the life of electrical components due to the stresses of heating and cooling.

In addition, newer LaserWriter models include energy saving modes that allow the printer to remain on, and still use very little power.

In Apple's offices, most LaserWriter printers are powered on for months at time. Some have been on for over a year with no need for increased maintenance.
Published Date: Feb 18, 2012

SCSI: Maximum Cable Length & Extenders Between Devices

What is the maximum cable length and number of SCSI cable extenders allowable between SCSI devices?
This article has been archived and is no longer updated by Apple.
The maximum distance between SCSI devices is two meters. This can be increased to six meters if there is only one SCSI device on the bus.

Typically, extender cables are 1 meter in length. So, there could be 6 extender cables between two devices, such as a computer and hard drive.

Note: Both the Peripheral Interface Cable and the Cable Extender have a straight-through pin configuration (1-1, 2-2, 3-3, and so forth), though pins 10, 12-15, 17, 35-37, 39, 40, and 42 are not connected.
Published Date: Feb 18, 2012

Macintosh: OK to Use SIMMs that Are Faster than Required

Can using SIMMs faster than what a Macintosh is officially rated for cause any problems?

This article has been archived and is no longer updated by Apple.

Using SIMMs that are faster than a computer's rating should not cause any problems. It's like arriving at the bus stop 10 minutes early--you'll just be there with time to spare but it won't make the bus arrive any earlier. In the same way, your data will be ready for the CPU faster, but the CPU won't read it until it's ready.

As long as your SIMMs are good quality and the proper resistors have been clipped, there should be no problem using faster speeds.

Published Date: Feb 18, 2012

LaserWriter II: Shortest Possible Envelope Size is 6.5 Inches

What is the shortest size envelope that I can feed into a LaserWriter II?

This article has been archived and is no longer updated by Apple.
The absolute shortest envelope size would have to be slightly longer than the distance between the transfer Corona's last feed roller and the Fuser Assembly. For the LaserWriter II engine, this distance is 6.5 inches.

Published Date: Feb 18, 2012

Personal LaserWriter: European-Size Paper Tray Availability

I want to use European-size paper (8 7/8 x 12 5/8 inches) in my Personal LaserWriter NT's cassette tray. Is this possible? I couldn't find anything in the spec sheets.

This article has been archived and is no longer updated by Apple.
Apple Service has a European paper tray in the A4 and B5 sizes. The part numbers can be found in the Service Programs binder under the Personal LaserWriter section. Determine which size you need, then contact Customer Service Administration to place an order.

Published Date: Feb 18, 2012

Apple Hard Disk: Changing The Desktop Icon

Where is the hard disk icon resource located? I want to go in and change it with ResEdit, but I can't seem to find it.
This article has been archived and is no longer updated by Apple.
Under System 6, changing the icon on any icon required a utility like ResEdit to modify. The location of the hard drive icon depended on where the manufacturer decided to put it. For example, with La Cie drives, the icon is made available to users for changing.

For Apple drives there was a custom resource in the SCSI Setup that puts the icon in the boot blocks of the drive. Changing the hard drive icon using a resource editing utility is not recommended by Apple.

With System 7 systems, changing the drive icon is as easy as copying an icon or picture into the Clipboard, opening Get Info on the drive, clicking on the icon, and pasting the icon you have in your Clipboard. You will not be able to change the icon if the drive is shared, or locked.
Published Date: Feb 18, 2012

TA46013_LisaWrite_Disappearing_Text_(TIL00735).pdf

LisaWrite: Disappearing Text

This article has been archived and is no longer updated by Apple.
On rare occasions, lines or possibly even pages of text may disappear from the screen of a LisaWrite document for no apparent reason. If the text has been cut, merely paste it back into the document. If the text hasn't been cut, open the page layout menu and select Don't Preview Pages. Your missing text should reappear after you select Save and Continue from the File Print menu.

There are also rare occasions when a line of text may not be printed at the bottom of a page. Selecting Save and Continue should correct the problem. If it doesn't, adjust the paragraph spacing in the line (with the Format menu) or insert a page mark (with the Page Layout menu), and then repeatedly choose Save and Continue until the line prints successfully.

Apple II: 80 Column Card Cannot Handle Some "Color" Programs

I have an Apple IIe, an Enhanced 80 Column card, and an Apple Color Monitor 100. I have two games, Batman and Hunt for Red October, that do not display in color even though they are both advertised as able to run on the Apple II with double high-resolution color graphics.

This article has been archived and is no longer updated by Apple.
The problem is that your software is trying to write directly to the video circuitry instead of using calls to the software. The 80 column card cannot handle these kinds of requests.

There are only two possible fixes:

* Get a different type of monitor and video card

* Call the software companies and ask if they have a software patch.

Appleworks GS: Is Compatible with Older Appleworks Files

Does Appleworks GS open older Appleworks files?
This article has been archived and is no longer updated by Apple.
Yes, AppleWorks GS opens older Appleworks files. You will need to use the Import function of Appleworks GS to do this.
Published Date: Feb 18, 2012

LaserWriter IISC: Use QuickDraw GX to Network (10/96)

I want to connect my LaserWriter IIsc to an AppleTalk network. Can I do this using the AppleShare Print Server?

This article has been archived and is no longer updated by Apple.

No. The LaserWriter IISC and Personal LaserWriter SC printers were designed as stand-alone SCSI printers. With the standard LaserWriter drivers installed, you cannot use either printer on an AppleTalk network. However, if you install QuickDraw GX, you can use both printers over an AppleTalk network.

Article Change History:
15 Oct 1996 - Added QuickDraw GX solution.
Published Date: Feb 18, 2012

AppleShare Server: Which Server Files Ought Be Backed Up

I want to do a full, unattended backup of my AppleShare server, but my backup software only lets me backup my Server Folder separately.

What files in the Server Folder, if any, need to be backed up on a continuous basis?
This article has been archived and is no longer updated by Apple.
AppleShare has two important sets of configuration information. The first is the Users and Groups data file, which is stored in the Preferences Folder of the system folder.

The second is folder permission information. On read and write volumes, this information is in an invisible file at the top level of the volume called "AppleShare PDS." On read only volumes, the information is stored inside "System Folder:Preferences:File Server." There is a PDF file for every volume that has been mounted while AppleShare was on.

You should back up both the Users and Groups data file, and the File Sharing folder as well.

Macintosh: The Dangers of Drag-Copying System Folders

By not using the Installer program to install a Macintosh System on a hard disk, what potential problems might I run into?

Also, is there any way to tell if a Macintosh System was installed correctly or drag-copied?

This article has been archived and is no longer updated by Apple.
When a System is drag-copied onto a disk rather than installed using the Installer, the System becomes unstable. There are several symptoms:

* The System bombs often.

* The System hangs without error messages.

* Applications unexpectedly quit.

There is no way to tell which Systems have been installed using the Installer and which have not. The best thing to do is to remove a suspect System Folder and reinstall using the Installer application.

Published Date: Feb 18, 2012

Macintosh Plus: SCSI Hard Drive Recognition Problem

I have a Macintosh Plus, with an external SCSI hard drive that has worked reliably for over a year. Suddenly the Macintosh won't recognize the drive, though both the Macintosh Plus and hard drive work fine separately (for example, using the hard drive with a Macintosh SE).

This article has been archived and is no longer updated by Apple.
Most probably something has blown the IC on the hard drive's analog board that controls the SCSI reset line. Since the Macintosh Plus (and the Macintosh Portable) doesn't have SCSI termination power, this problem can only be fixed by replacing the hard drive assembly.

Published Date: Feb 18, 2012

TA46020_Macintosh_IIci_Speeding_Up_Bit_Graphics_(TIL07359).pdf

Macintosh IIci: Speeding Up 24-Bit Graphics

Which speeds up a Macintosh IIci's 24-bit graphics more: a cache card or a Macintosh Display Card 8*24 GC?

This article has been archived and is no longer updated by Apple.
By far the best choice for speeding up 24-bit images is the Macintosh Display Card 8*24 GC. Off-loading the graphics processing from the central processor speeds up screen imaging and "number crunching" (as neither is interrupting the other).

Ethernet Card: Determining a Card‘s Address

How can I determine the address of an Ethernet card? Is there a software utility that does this?
This article has been archived and is no longer updated by Apple.

Printed on Board

The network address of some Ethernet card is on a printed label on the back of the Ethernet circuit board.

EtherPeek

You can obtain the AG Group EtherPeek network monitoring application, which includes a utility called it GetMyAddress. This will also return the address of the Ethernet card.

MacTCP

Users who use MacTCP may be able to identify the Ethernet address by opening the MacTCP control panel and pressing the Option key when selecting the Ethernet Icon. For this to work you must be sure the caps lock key is NOT depressed.

Open Transport 1.1 or Later

If you are using Open Transport (version 1.1 or later), you can obtain the Ethernet address by opening the AppleTalk control panel and selecting Get Info from the File menu.

Apple LAN Utility

You can use the Apple LAN Utility to report the burned in address without being connected to a network.

Published Date: Feb 18, 2012

LaserWriter: Font Substitution Printing Problem

I have suddenly begun experiencing printing problems on my LaserWriter. When I try to print with Adobe fonts, the system responds that it is "substituting a bit mapped version, as the printer font can't be found". The LaserWriter then prints using the Courier font.

This problem happened after I did some work on my System file. I was having a font ID conflict, so I removed all but the required fonts then reinstalled the fonts one-at-a-time.

Of course, all my printer fonts are in a Printer Folder.

This article has been archived and is no longer updated by Apple.
This sounds like your PostScript fonts are not downloading. Are your fonts in the System Folder or in a folder in the System Folder? Put them at the first level of your System Folder; don't embed them in another sub-folder.

Also, be sure font substitution is off in your Page Setup dialog box.

Published Date: Feb 18, 2012

LaserWriter IINTX: Font Utility Shows When You‘re Out of Storage

I have a hard disk attached to my LaserWriter IINTX. I know that I'm using 80% of my disk space for caching and only 20% for font storage. Does this mean I only have room for 8MB of fonts on a 40MB hard disk?

This article has been archived and is no longer updated by Apple.
Your hard disk has room for only 8MB of fonts. The Font Utility application gives you a warning when the disk is getting too full. If you have several large fonts, you might not be able to get 8MB of fonts on the drive before the utility tells you you're running out of room.

Published Date: Feb 18, 2012

LaserWriter IINTX: How It Allocates Disk Space

I have a 40MB hard drive attached to a LaserWriter IINTX. Is it true that only 20% of the storage space is used for fonts while the other 80% is used for caching?

This article has been archived and is no longer updated by Apple.
A hard disk attached to a LaserWriter IINTX gets initialized with 20% of the disk space dedicated to font storage and 80% to font caching. The LaserWriter Font Utility tells you how much space is available for additional font storage.

The "diskstatus" operator gives the number of pages currently available and the maximum number of pages available (a page being 1024 characters). The operator "userdiskpercent" returns the percentage of disk space allocated for user files.

The operator "setuserdiskpercent" allows you to set the percentage of user file space on the drive. It also removes the least-recently used cached bitmaps from the hard disk until there is enough free space available.

Published Date: Feb 18, 2012

Apple IIGS: High Speed SCSI Card Not Recognizing Hard Drive

I'm using a High Speed SCSI card on my Apple IIGS. The problem is my CMS 60MB hard drive isn't being recognized by the SCSI card.

This article has been archived and is no longer updated by Apple.
Check how much RAM the Apple IIGS has: to support the High Speed SCSI card, an Apple IIGS must have a minimum of 768K.

Also, check DIP switch 8 on the CMS drive. It controls the reset line, which is pin 40. All Apple SCSI cards use the reset line for handshaking. If this pin is disconnected or turned off, the Apple IIGS won't recognize the hard drive. Be sure that switch 8 on the CMS hard drive is in the closed position.

If switch 8 is in the closed position and you still do not get recognition of the hard drive, check the SCSI switch to make sure it is not set to 7.

Published Date: Feb 18, 2012

HyperCard: RAM Cache Launching Issues

While trying to launch HyperCard 1.2.5 under System 6 with the RAM Cache ON, I only get a menu bar that says "HyperCard". The menu doesn't really work and my computer locks up. If I turn RAM Cache OFF, HyperCard launches just fine.

Removing all the INITs from the System Folder doesn't help.
This article has been archived and is no longer updated by Apple.
There is no known problem using the RAM Cache with HyperCard, so your problem is probably a corrupted HyperCard file. Try these steps:

1) Rebuild the desktop.

2) Use a new Home card.

3) If you're still having problems, replace your HyperCard application.
Published Date: Feb 18, 2012

HyperCard: Dial Command Problems with Macintosh Portable Modem

I'm having problems using the Apple Internal 2400 baud modem with the Macintosh portable. The HyperCard Phone stack's dial command just doesn't seem to work with this modem.

This article has been archived and is no longer updated by Apple.
Make sure that the 10-second pause is in the "doDial" handler. Before "put empty", the last line of code in the handler, insert these lines:

```
wait 10 sec
send return to HyperCard
```

This way the change takes place only once, and it's easier to follow the code at that point. The "return" causes the modem to drop the line, leaving you in voice mode.

The problem with the modem and the Phone stack is that HyperCard opens the serial port for three seconds. It takes the modem around two seconds to go off hook. The dial string contains a comma creating a one-second pause. This leaves hardly any time to send the phone number. The phone number is incompletely transmitted and you get disconnected.

We suggest you use the Serial XCMDs available from APDA for sending data to modems. This command set gives you complete control over the serial port, eliminating the need for the 10-second pause to get the modem to release. (You'll need to recreate the doDial handler to use the serial XCMDs.)

Macintosh: Proper SCSI Termination for Powered-Off Devices

I'm using a Montage FR1 slide maker connected via the Macintosh SCSI port. My Macintosh won't boot if the FR1 is off. I don't want to leave the slide maker on all the time. What can I do?

This article has been archived and is no longer updated by Apple.

The SCSI bus requires termination power to provide clean, quality SCSI signals. When a SCSI device has its own termination power, the SCSI bus signals are corrupted when the device is off because this leaves the SCSI bus unterminated. An non-terminated SCSI bus can cause startup problems because of noise on the bus.

Sometimes, a SCSI device supplying its own termination power can remain off at startup because it has a relatively clean SCSI bus signal. But there is no guarantee that the bus signals will stay clean and uncorrupted, as it is improperly terminated in this situation.

SCSI devices that use Macintosh termination power can be off and still be properly terminated.

Lisa: Format for Printer

This article has been archived and is no longer updated by Apple.
When printer format settings are made for a document, other blank documents and stationary pads may also change their printing formats to the new settings.

This can only happen to documents or stationary pads, such as the LisaWrite stationary pad, that have never had text or data entered into them. The printer format settings of non-empty documents and stationary pads will not change unless specifically set by the Format for Printer dialog box while the document is open.

Macintosh: Parity Checking Not Needed By Average Users

What is the difference between a plain Macintosh IIci and a Macintosh IIci with parity?

This article has been archived and is no longer updated by Apple.
The only difference is that one machine has parity checking and the other does not. RAM parity detects single-bit errors in RAM and prevents operation with damaged data or instructions. This type of error checking detects "soft errors" and intermittent "hard errors". Most soft errors are caused by atmospheric conditions, but the reliability of current DRAM is high enough that these conditions are VERY rare. Bad RAM chips are almost always found during Macintosh startup without using parity checking.

Apple has never used ECC (Error Correction Code) schemes to detect errors in System RAM. The Macintosh IIci and Macintosh IIfx (parity models) are the first Macintosh computers to use any kind of memory error checking during normal operation.

Apple implemented parity checking as an option for the Macintosh IIci and Macintosh IIfx as a result of government requirements. Average users won't need parity checking.

For more information, search under "Parity Checking".

System 6.x: Ways to Change System Memory Configuration (1/95)

I have a Macintosh IIci with 4 MB of RAM that is crashing frequently when using Microsoft Excel 2.2. I called Microsoft and they told me I needed to increase the size of my System file's memory partition under MultiFinder. How do I do this??

This article has been archived and is no longer updated by Apple.
There's only one of two memory allocation changes that Microsoft could be referring to:

1) The memory allocation for Excel

2) The memory allocation for Finder

We suggest that you try these options by using the Get Info dialog in the Finder. If neither of the above options work, you should perform a clean system install.

Apple II: LocalTalk ImageWriter Delay from BASIC (2/97)

I'm running an Apple IIGS lab (28 systems) with seven LocalTalk ImageWriters.

When using Applesoft BASIC, my computers print properly with a "PR#1" command. However, there is a 30-second delay from the time one computer finishes printing until the next system is allowed to print.

Here is a test program that I'm using:

```
10 PRINT CHR$(4);"PR#1"
20 FOR I=32 TO 126
30 PRINT CHR$(I);
40 NEXT:PRINT
50 PRINT CHR$(4);"PR#0"
```

If I run the above test program simultaneously on two Apple IIGS computers trying to print to one LocalTalk ImageWriter, the first computer to type "run" prints fine. The other computer has to wait for the LocalTalk option board to release the printer.

I have gone through the ImageWriter technical book and can't find anything that allows the LocalTalk card to release the printer Immediately after the "PR#0" command.

Is there a reset or release command that I can add to the program to eliminate this wait?

This article has been archived and is no longer updated by Apple.

You are experiencing the time it takes the ImageWriter to release after the connection to the computer is lost. Your problem is that the "PR#0" command just changes the mode of the computer; the printer still thinks the first computer should be there.

The printer has a built-in timeout that can't be changed. Something you might try is to insert an "ESC c" as line 45. This command resets the printer and might cause the printer to drop its connection before the computer does.

TA46034_ImageWriter_Cant_Use_Null_Code_(TIL07374).pdf

ImageWriter: Can‘t Use Null (00) Code

Can the ImageWriter II do anything with a null (00) code?

Is there anything I can send to the ImageWriter II to simulate the old "bell" ACSII function?

This article has been archived and is no longer updated by Apple.
The ImageWriter can't do anything with a null (00) code. There is nothing you can send to the printer to simulate the "bell" ASCII function because the printer has no speaker.

LaserWriter IINTX: ROM Upgrade Supports Dynamic Soft-Switching

I understand that the new LaserWriter IINTX ROM upgrade supports software switching between emulation modes and ports. Does this mean that a LaserWriter IINTX can connect simultaneously to a LocalTalk and PS/2 serial port? While the product update sheet makes this sound possible, the LaserWriter manual (Appendix F, page 133) seems to say that you must disconnect the LocalTalk connector when using the serial port.

This article has been archived and is no longer updated by Apple.
Yes, this will work. The LaserWriter should ignore the "other" port, and only listen to the active port. The soft-switching capability enable/disable the ports correctly, as will the DIP switches.

To our knowledge, there isn't any software on the market that automatically takes advantage of this feature. If you want to take advantage of this feature, you'll have to write the PostScript code (there are examples of such code in the LaserWriter Owner's Guide).

There is a consideration: The LaserWriter needs to receive the code to change modes from the system connected to the active port. This means that both an MS-DOS machine and a Macintosh need to have the code, and each will tell the LaserWriter to listen to the other computer.

All in all, a much better solution is to use a single interface for all machines. LocalTalk is your best solution, with a LocalTalk interface card installed in the MS-DOS system.

LaserWriter: Maximum Printable Area is 6.75 x 13.0 Inches

Why can't I print anything larger than 8.5 x 14 inches on my LaserWriter?

This article has been archived and is no longer updated by Apple.
The maximum printable area of a LaserWriter is 6.75 x 13.0 inches when centered on an 8.5 x 14 inch page.

The LaserWriter II engine has a minimum left, right, top, and bottom margin of 0.197 inches. This gives the LaserWriter II a printable area of 8.106 x 13.606 inches. So, the only way to get a larger print area is to use a LaserWriter II series printer.

Macintosh Portable: External Hard Drives and "Sad Mac" Errors

Are there problems with connecting an external SCSI hard drive to the Macintosh Portable? I have a Macintosh Portable with an internal 40MB drive. When I tried to connect a 45MB external drive, the Macintosh Portable refused to boot. The "Sad Mac" icon came up with the error code: 0000000F 00000002.

The hard drive is a Jasmine Direct Drive 45 that has been with a Macintosh Plus. I checked the usual things: The external hard drive was powered up and running before I powered on the Portable. There was no System Folder on the external hard drive. The drive was terminated and had a unique SCSI ID.

Am I overlooking something? Can the Portable support an external hard drive?

This article has been archived and is no longer updated by Apple.
The Macintosh Portable can access and use any external SCSI device that a Macintosh Plus can access. There may be an issue with the SCSI driver on the hard drive and compatibility with the Portable boot ROMs, but we do not have any information on this problem.

The error message you gave above is roughly equivalent to an "ID=02" -- meaning that you can't really use it seriously to diagnose the problem. It does tell you that some piece of recently-loaded software got clobbered, but it's a guess to say whether it was due to software corruption, SCSI signal problems, incompatible drivers, or all of the above.

The best thing to do when getting this kind of error message is contact the third-party's service organization for any possible information on driver compatibility.

Responder: Changing a Macintosh Network Name

Article Change History

05/14/92 - RETITLED
* For clarity.
08/25/92 - REVIEWED
* For technical accuracy.

A customer has a Macintosh set up as a workstation on an AppleShare network. When the Responder asked them to name the computer, they did that. Now they need to change the name on that computer that the Responder recognizes. We can't get Responder to allow them to rename the drive. None of the following worked:

- deleting the Responder file and copying a new one to the system.

- deleting the Responder file and then reinstalling from the system installation disks.

- starting up from a system floppy, deleting the System, Finder, and Responder files, then reinstalling the system.

This article has been archived and is no longer updated by Apple.
There is no need to throw away any files to change the network name of a Macintosh. The procedure differs, depending on the version of System software:

- With System 6, the easiest way to rename the Macintosh is to open the Chooser and type a new name in the "User Name:" field. The new name is not used until the Macintosh is restarted.

- With System 7, open the Sharing Setup control panel and change the "Macintosh Name:" field. The new name is used immediately.

With both System 6 and System 7, the name is stored in the System file in an STR resource with an ID of -16096. When starting up under System 6, if the Macintosh has no name, the Responder will ask the user to type in a name. If a name is typed in, the Responder will write the name to the resource STR ID = -16096. System 7 does not do this. The only way to name the Macintosh is via the Sharing Setup Control Panel.

ImageWriter II: Troubleshooting "Printer is not responding"

I'm using an ImageWriter II with a Macintosh Portable. I keep getting the message. "Printer is not responding. Check the select switch", but my select switch is on.

This article has been archived and is no longer updated by Apple.

If there is nothing wrong with your ImageWriter II, there are three possible causes for this problem:

* A defective printer cable.

* A defective printer port on the Macintosh Portable.

* Incorrectly set software.

The most common of the three causes is incorrectly set software. Be sure you have selected the proper ImageWriter driver--not the AppleTalk ImageWriter--in the Chooser, and confirm that it is in the selected port, either printer or modem.

LaserWriter IINTX: ROM Upgrade Ordering Information

How can I get the latest PostScript upgrade for the latest LaserWriter IINTX?
This article has been archived and is no longer updated by Apple.
The formal LaserWriter IINTX 3.0 ROM upgrade kit (Apple part number M0445LL/A) was discontinued several years ago. Although an upgrad kit is not available, the individual LaserWriter IINTX ROMs are listed on the Apple service price pages and can be ordered and installed by authorized service providers.

In order to upgrade a LaserWriter IINTX from an earlier ROM version a total of 8 new ROM's need to be purchased. The service part numbers for the ROM's are:

Service Part Number	Description
341-0711	IC, ROM,LL0, LW IINTX 3.0
341-0712	IC, ROM,HH0, LW IINTX 3.0
341-0713	IC, ROM,LL1, LW IINTX 3.0
341-0714	IC, ROM,HH1, LW IINTX 3.0
341-0715	IC, ROM,LM0, LW IINTX 3.0
341-0716	IC, ROM,HL0, LW IINTX 3.0

PrintMonitor: Why=6 and Why=-120 Error Messages

My PrintMonitor is giving me the error codes of Why=6 and Why=-120. What do these mean?
This article has been archived and is no longer updated by Apple.
PrintMonitor error messages can actually be decoded if you have a list of Macintosh system errors. The "why" (or y=) portion is the system error number.

Why=-120 means "Directory Not Found". Why=-120 may be the result of a corrupt directory structure on your local hard drive. Rebuilding the Desktop may solve the problem, or you may have to backup, reformat, or restore the drive.

Why=6 means "overflow trap error" and is pretty general and not much to go on. With Why=6 it's more important to know what else was going on that may have caused a conflict (such as what applications are running and what INITs and cDEVs are on the system). You may be seeing an incompatibility, memory conflict, or just general system corruption. Trashing and reinstalling the System with the Installer usually takes care of this.

Macintosh SE: Third-Party 80ns SIMMs Can Cause Problems

I'm putting a 2MB RAM upgrade into my Macintosh SE. I started out with four 120ns 256K SIMMs. I'm putting two 80ns 1MB SIMMs into slots one and two and am putting the other two 120ns 256K SIMMs into slots three and four.

At power-on, my screen shows vertical lines spaced evenly across, about 1/4 inch apart. These lines appear right away, even while showing the "happy Mac" icon. With the lines visible, I can choose "About the Finder" and it indicates that the Macintosh SE is recognizing all 2.5MB of RAM.

Should I not be mixing 80ns and 120ns SIMMs with a standard Macintosh SE?

This article has been archived and is no longer updated by Apple.
We have had reports of third-party 80ns memory having strange effects on Macintosh SE computers. In all of the cases, the problem was defective memory modules. The first thing to do is replace the 80ns SIMMs with new ones. If the problem still continues, try using slower 1MB SIMMs.

Published Date: Feb 18, 2012

Macintosh: Why It Doesn‘t Use Entire Screen?

Why is there a 10-millimeter unused border around the edge of Macintosh monitors? Why doesn't the Macintosh use its entire available screen space?

This article has been archived and is no longer updated by Apple.

This is because of image resolution quality and aspect ratio concerns. The Macintosh screen has to have certain dimensions. If the projected image were to completely fill the screen, it would be slightly distorted, especially at the edge of the screen. Most computer displays have a mask around the border area to provide the largest and clearest usable area.

Macintosh: SCSI Devices Cannot be Shared Between Computers

Is there any way a single SCSI device can be connected to two Macintosh computers, with a switch box for example?

This article has been archived and is no longer updated by Apple.

The SCSI protocol doesn't allow dynamic switching or interruption of the power and signal lines in the cable. For this reason alone, a switch box would create havoc in a SCSI chain -- at the minimum causing all types of data transfer errors and possibly even blowing a device. We know of no way to connect one SCSI peripheral to two computers.

Applesoft Internals: Floating Point Math Package (1 of 2)

Applesoft's floating point package provides a 9 digit scientific package for evaluating numeric equations. It supports trigonometric functions with arguments in radians, exponents and logarithms to base e.
This article has been archived and is no longer updated by Apple.

ABBREVIATIONS

msb: most significant bit or byte
lsb: least significant bit or byte
eol: end of line token ($00)

A: the 6502 accumulator
X: the 6502 X register
Y: the 6502 Y register
Z: the zero flag of the 6502 status register
C: the carry flag of the 6502 status register

A,X is a 16 bit number where A has the msb and X the lsb.

(Y,A) is the number or string whose address is in Y and A, with the msb in Y and the lsb in A.

FAC: the floating point accumulator
ARG: the ARGument register

REAL NUMBER FORMAT

The real number format used throughout Applesoft is: the exponent is a single byte signed number (EXP) in excess of $80 form (the signed value has $80 added to it); the mantissa is 4 bytes (HO,MOH,MO,LO); the binary point is to the right of the most significant bit. Since in binary floating point notation the msb is always 1, the number's sign replaces the msb when the number is stored in memory in packed form. The sign, though, is kept in a separate byte (SGN) when only bit 7 is significant. If the exponent is zero, the number is zero, although the mantissa isn't necessarily zero.

Examples:

EXP HO MOH MO LO SGN

Packed format
-10 84 A0 00 00 00
10 84 20 00 00 00

FAC format
-10 84 A0 00 00 00 FF
10 84 A0 00 00 00 00

Arithmetic routine calling conventions for single argument functions (e.g., SGN, ABS or INT):

On entry the argument is in the FAC.
On exit the result is in the FAC.

Arithmetic routine calling conventions for two argument functions (e.g., FADD and FSUB):

On entry the first argument is in the ARG.
On entry the second argument is in the FAC.
On exit the result is in the FAC.

FLOATING POINT REGISTERS

NOTE: The TEMP locations may be used for other things when not used by the floating point math package.

.	FAC	ARG	TEMP1	TEMP2	TEMP3	RND
EXP	9D	A5	93	98	8A	C9
HO	9E	A6	94	99	8B	CA
MOH	9F	A7	95	9A	8C	CB
MO	A0	A8	96	9B	8D	CC
LO	A1	A9	97	9C	8E	CD

SGN	A2	AA	(packed format)

FLOATING POINT CONSTANTS

The following addresses point to useful numbers; they're packed and suitable for use by most of the arithimetic routines including CONUPK and MOVMF.

RND	00C9
-32768	E0FE
1	E913
SQR (1/2)	E92D
SQR (2)	E932
-1/2	E937
LN (2)	E93C
10	EA50
1000000000	ED14
1/2	EE64
LOG (2) base e	EEDB
pi/2	F063
pi*2	F06B
1/4	F070

FLOATING POINT REGISTER MOVE ROUTINES

MOVFM EAF9
Moves the number in memory Y,A points to into FAC. On exit A and Z reflect FACEXP.

MOV2F EB1E
Pack FAC and temporarily moves it into register 2. On exit A and Z reflect FACEXP.

MOV1F EB21
Pack FAC and moves it temporarily into register 1. On exit A and Z reflect FACEXP.

MOVML EB23
Pack FAC and move it into zero page area starting at X. On exit A and Z reflect FACEXP.

MOVMF EB2B
Pack FAC and move it into memory pointed to by Y,X. On exit A and Z reflect FACEXP.

MOVFA EB53
Move ARG into FAC. On exit A and Z reflect FACEXP.

MOVAF EB63
Move FAC into ARG. On exit A and Z reflect FACEXP.

CONUPK E9E3
Load ARG from memory pointed to by Y,A. On exit A and Z reflect FACEXP.

SUMMARY OF MOVES:

FAC => (Y,A) EB2B MOVMF
FAC => (0,X) EB23 MOVML
FAC => TEMP1 EB21 MOV1F
FAC => TEMP2 EB1E MOV2F
FAC => ARG EB63 MOVAF

ARG => FAC EB53 MOVFA

(Y,A) => FAC EAF9 MOVFM
(Y,A) => ARG E9E3 CONUPK

FLOATING POINT OPERATORS

The following routines require that A and Z reflect FACEXP. Even though FAC move routines set up A and Z, a LDA $9D will insure their proper values.

FMULT E97F
Multiply the FAC by the number in memory pointed to by Y,A.

FMULTT E982
Multipy FAC and ARG. On entry A and Z must reflect FACEXP.

FDIV EA66
Divide the number in memory pointed to by Y,A by FAC.

FDIVT EA69
Divide ARG by FAC. On entry A and Z must reflect FACEXP.

FADD E7BE
Add the number Y,A points to in memory to FAC.

FADDT E7C1
Add FAC and ARG. On entry A and Z must reflect FACEXP.

FSUB E7A7
Subtract FAC from the number Y,A points to in memory.

FSUBT E7AA
Subtract FAC from ARG. On entry A and Z must reflect FACEXP.

Macintosh: How To Get Two Screen Dumps on a Single Page

Is there any way to get a Macintosh to do two screen prints on a single page?

This article has been archived and is no longer updated by Apple.

There is no way to automatically get two screen prints on the same page. Because the screen dump is a MacPaint file, you can cut and paste the two documents into one and print the resulting document.

Published Date: Feb 18, 2012

Macintosh SE/30: Screen Bowing Problems

My Macintosh SE/30's screen bows on the sides when there is a black rectangle displaying. This happens, for example, in Excel when I select three or more cells and highlight a whole row across the entire screen. When I deselect, the bowing stops.

I've replaced the analog board, the power supply, the video board, the CRT, and disconnected the hard drive--all to no avail. Is it possible that the system board is receiving interference from something else in the system?

This article has been archived and is no longer updated by Apple.
The problem you're describing is usually caused by one of three things:
* defective analog board,
* defective video board, or
* internal contrast setting set too high.

Even though you've already replaced these components, we suggest you recheck them (particularly the video board) for possible defects.

Though the logic board is a possible cause for this type of problem (since it maintains the video image in VRAM) it is unlikely to be causing the problem. If the first set doesn't solve the problem, however, then go ahead and replace the logic board.

EMI: What You Can Do To Prevent Screen Interference

I am getting screen interference on my computer from a transformer outside my home. I have tried all sorts of surge supressors, all to no avail. Any other suggestions?

This article has been archived and is no longer updated by Apple.

Is your interference coming directly from power lines or from electromagnetic interference (EMI) in the air? If it's from power lines, you'll need a "high-end power filter" costing around $200 and up.

Your problem sounds like general electromagnetic interference. The only thing you can do is move your monitor as far away as possible from the source of interference. You can also try putting some shielding around the monitor to protect it from EMI.

System 7 Chooser: Device, Name, Zone, Memory Limits

This article discusses device, name, and zone limits as displayed and controlled through the System 7 Chooser, with some additional notes on the limits of previous versions of the Chooser.

This article has been archived and is no longer updated by Apple.

The following information pertains mostly to the System 7 Chooser (use at least version 7.0 of the Chooser, preferably 7.1 or greater), with some comparative information on the System 6 Chooser:

The Chooser DA window consists of four separate sections:

1) The device type list.
2) The AppleTalk zone list (visible only if there are multiple zones).
3) The AppleTalk active/inactive controls.
4) The available devices name list.

1) The Chooser is able to display a maximum of 32 items in the Chooser device type list (Note: The System 6 limit was 16). This is the limit that is imposed by the Chooser itself, not by something interfering with the operation of the Chooser. If, for instance, you have more than 16 Chooser items in your System Folder under System 6 and only 16 show up, there is no conflict. Sixteen is simply the limit under System 6.

2) The Chooser allocates memory for the zone list dynamically, up to 32K (Note: this is the same as the System 6 Chooser). Each entry in the zone list uses 1 byte of memory for each character in the zone name, plus 1 byte. The Chooser uses this extra byte as a length byte. For example, the 7-character zone name "My Zone" uses 8 bytes of memory: 7 bytes for the characters and 1 byte for the length byte. The maximum length of a zone name is 32 characters. A 32-character zone name uses 33 bytes of memory.

   Based on this information, if every zone had a 32-character name, it would be possible to have a maximum of 992 zones listed in the Chooser (32,768 / 33 = 992.97, remove the remainder). The maximum number of zones that can be displayed in the Chooser is wholly dependent on the length of the zone names being used.

3) This one is self-explanatory; it controls whether or not AppleTalk is active (Note: this is the same as the System 6 Chooser).

4) Determining the maximum number of visible Chooser device names:

   The System 7 Chooser allocate a 32,768-byte buffer for the Chooser's list of available AppleTalk network device names (Note: the System 6 Chooser allocated a 512-byte buffer). Each name in the buffer is embedded in an AppleTalk Name Binding Protocol (NBP) packet received by the Chooser from the selected device type. The NBP packet is called a "lookup reply", and is sent in answer to the Chooser's lookup broadcast for the selected device. An example is the selection of the device type LaserWriter driver, and the displayed LaserWriter object names.

   The buffer space used by each returned AppleTalk device is the length of the NBP reply packet returned by the device to the Chooser's lookup.

   NBP LaserWriter Lookup Reply Packet Definition

Function and Tuple Count:	1 byte
NBP ID:	1 byte
Network Number:	2 bytes

Node ID:	1 byte
Socket Number:	1 byte
Enumerator:	1 byte
Object Field Length:	1 byte
Object:	length of name
Type Field Length:	1 byte
Type:	11 bytes for type "LaserWriter"
Zone Field Length:	1 byte
Zone:	1 byte for zone "*" the NBP reply default
TOTAL	22 bytes + length of the LaserWriter name

A calculation for determining the maximum number of visible LaserWriters in a zone:

Number of visible LaserWriters = trunc(32,768/(22+(sum of name lengths / Number of LaserWriters))

If the LaserWriter names are all the same length, the calculation is simplified to trunc(32,768/(22+length)). The mean calculation (sum of name lengths / Number of LaserWriters) is not necessary in this case.

(NOTE: Trunc indicates that decimal values should be ignored. That is, a result of 780.19 indicates 780 LaserWriters.)

The calculation can be used for any other type of AppleTalk device, if the type length and the mean of the device names are known.

System 7 Chooser selecting the Apple LaserWriter driver displays:

Mean Name Length	Max Number of Visible LaserWriters
32	606
30	630
25	697
20	780
15	885
10	1024
5	1213

For information on the System 6 Chooser limits, search on System 6 Chooser.

System 7: System 7.0-7.1.2 Preferences, Defaults & Location

This article describes the default preference settings of System 7.0 through System 7.1.2.

You can customize your Macintosh in a variety of ways to suit your own personal style. For example, you can change ways in which information is displayed, the sounds your system makes, and how it handles file management. Your Macintosh uses a variety of Preferences files to maintain your custom settings.

There are several preference settings under System 7. System-wide preferences, such as mouse-tracking speed, are set via Control Panels, but are stored in Parameter RAM (PRAM). Preferences specific to the Finder are also set via Control Panels, but are stored in a file called Finder Preferences located in the Preferences folder, in the System Folder.

Here is some information on where each preference is stored, along with instructions for resetting both system-wide and Finder preferences.
This article has been archived and is no longer updated by Apple.

System Preferences

This table lists system-wide preferences that may affect all applications:

NOTE: Items marked with an asterisk (*) (the last items in the table) apply to the PowerBook.

PREFERENCE	LOCATION	DEFAULT
32-bit addressing	Memory Control Panel	24-bit addressing
Disk cache size	Memory Control Panel	6K
Brightness settings	Brightness Control Panel	Mid-range on the slider
Highlight color	Color Control Panel	Black
Cursor blink rate	General Control Panel	Middle setting
Menu blink count	General Control Panel	3 times
Date, time, and displayed format	General Control Panel and Alarm DA	None
Keyboard repeat rate and repeat delay	Keyboard Control Panel	For repeat: One away from Fast For delay: One away from Long
Monitor settings and location of extra monitors	Monitors Control Panel	Primary monitor only; set to Black & White
Mouse tracking and double-click speeds	Mouse Control Panel	For tracking: Very Slow For double-click: Middle setting
Beep sound	Sound Control Panel	Simple beep, though it is not highlighted
Startup disk choice	Startup Disk Control Panel	None set, uses standard volume search method
Cache settings (68040 Macintosh)	Cache Switch Control Panel	Faster (Caches Enabled)
Minutes before system sleep*	PowerBook Control Panel	8 Minutes
Minutes before	PowerBook Control Panel	4 Minutes

hard disk sleep*		
Macintosh PowerBook rest*	PowerBook Control Panel	Rest (While in the PowerBook Portable Control Panel, hold down the Option key and click Minutes Before System Sleep.)
Stay awake when plugged in*	PowerBook Control Panel	Unselected
Modem selection	PowerBook Setup Control Panel	Internal modem
Wake on ring	PowerBook Setup Control Panel	Unselected (See Portable Control Panel for internal modem.)

Except for Date and Time and the default application font all system-wide preferences may be reset by resetting PRAM.

* To reset PRAM under System 7, hold down the Command-Option-p-r keys during start up (Make sure the Caps Lock key is up!). The Macintosh restarts shortly after displaying the "Welcome to Macintosh" screen, which indicates that PRAM has been reset.

Finder Preferences

PREFERENCE	LOCATION	DEFAULT
Font used for Finder view	Views Control Panel	Geneva 9
Icon alignment settings for Finder	Views Control Panel	Straight grid - "Always snap to grid" deselected
Icon list view settings for Finder	Views Control Panel	Smallest icon; display sizes, kinds, labels, and dates; deselect "Calculate Folder Sizes" and "Show Disk Info in Header"
Trash Can warning dialog	Setting in Get Info for the Trash Can	Warn before emptying

With the exception of virtual memory, these parameters may be reset by deleting the Finder Preferences file, which is located in the Preferences folder inside the System Folder. System 7 does not allow this file to be modified so if it is on the start-up disk, you need to disable it instead. To do this, drag the Finder Preferences file out of the Preferences folder and restart the Macintosh. System 7 creates a new Finder Preferences with default values automatically. You may then delete the old Finder Preferences file.

NOTE: The Virtual Memory, File Sharing, and Window Color settings are stored with their respective Control Panel files and cannot be reset using these methods. Virtual Memory and File Sharing can be temporarily disabled, however, by pressing the Shift Key while starting the Macintosh. Hold the key down until "Extensions Of" appears in the "Welcome to Macintosh" screen.

System 7: Short File and Folder Names for MS-DOS Access

The file and folder names in the Get Info dialog box are not the same as the name shown under the directories on the Finder desktop. When I click on the name in the Get Info dialog box, the name changes. Why?

This article has been archived and is no longer updated by Apple.

```
The file or folder you're viewing is located on a file server or is being
shared under System 7.  To allow both MS-DOS computers and Macintosh
computers to access file servers, all files and folders are named twice.

Since MS-DOS limits both the length and the kinds of characters in
file and folder names, we have to change the standard Macintosh names to
shorter versions that work under MS-DOS.  Clicking on the file or folder
name in the Get Info dialog box toggles between the Macintosh and MS-DOS
versions of the name.

Examples:
 Macintosh name = System Folder    Short name=!System.Fol
 Macintosh name = Cafe 7.0F        Short name=!Cafe_7.0F
```

System 7: Contiguous Memory with Virtual Memory in 24-bit Mode

Article Change History

08/19/92 - REVIEWED
* For technical accuracy.

What is the largest contiguous memory block available with virtual memory in 24-bit mode?

This article has been archived and is no longer updated by Apple.
In 24-bit mode using virtual memory, total RAM can be set up to 13MB, depending on the CPU and the number and placement of NuBus cards. This memory is not a contiguous block, however. The largest contiguous block will be roughly 7.5MB.

Viewing the About this Macintosh window can appear confusing because the totals for RAM used by programs may seem to add up incorrectly. A total of 16MB of RAM is addressable under System 7. Some of this is memory reserved for ROM (1MB), IO (1MB), video for the Macintosh IIci or Macintosh IIsi (1MB), and NuBus cards (1MB each). This memory is mapped starting above the 8MB mark. Any free memory in the upper 8MB of RAM (up to the 5MB possible) forms an "upper memory block."

Under System 7, system heap first loads into the bottom 8MB of memory then programs, starting with Finder, load into the upper memory block, provided there is a large enough contiguous block there to hold the program. If there is not a large enough contiguous block in the upper memory, the program will load in the lower memory block. Thus it is possible to have a lower unused block of about 7.5MB (the lower 8MB minus system heap) and an upper unused block of about 4MB (or less). Viewing About this Macintosh lists only the largest unused block of memory, not the total unused memory.

System 7: Ready,Set,Go! Compatibility

Article Change History

09/02/92 - CORRECTED
* Spelling of product name.

Is Ready,Set,Go! 4.5 fully compatible with System 7?

This article has been archived and is no longer updated by Apple.
Ready,Set,Go! 4.5a, which is listed as fully compatible in the "System 7.0: Compatibility With Selected Hardware and Software" booklet has some compatibility problems with printer drivers later than 5.2 (System 7 drivers are 7.0).

Non-PostScript pen lines and fills will not print and may result in the error message "Undefined error, Command-S 8. A PostScript error has been generated by the LaserWriter extension file. The document is OK but cannot be printed." PostScript pen lines and fills which are located to the far left of the Ready,Set,Go! menu work fine.

LetraSet will not be updating Ready,Set,Go! 4.5a, but will continue to support the product. They recommend Design Studio 2.0 as an upgrade.

TDD Modems

What companies manufacture modems that can communicate with deaf or hearing-impaired TDD (Telecommunication Device for the Deaf) users?

This article has been archived and is no longer updated by Apple.
Krown Research and UltraTec make 300-baud/TDD modems. You can find their addresses and phone numbers in separate articles in the Tech Info library by searching on their company names.

These modems require a special cable to connect to the computer. They can be used with a Macintosh or Apple II system equipped with an RS-232 serial port. Use the 300-baud modem setting.

You can use MacTerminal 2.3.1 with these modems. MacTerminal 3.0 will not work with the TDD modems.

For a normal modem to communicate with a TDD Modem, change the TDD settings to ASCII and 300 baud, and set the normal modem to 300 baud and TTY.

TA46069_Macintosh_IIsi_ThirdParty_Monitors_(TIL07425).pdf

Macintosh IIsi: Third-Party Monitors

What third-party monitors are compatible with the Macintosh IIsi?

This article has been archived and is no longer updated by Apple.
Most multisync monitors that are about 14" should work. There currently is no third-party two-page or portrait option available for the Macintosh IIsi's built-in video.

Here is a list of companies whose monitors work with the Macintosh IIsi's built-in video:

Mitsubishi
Relisys
Seiko
Sony
NEC MacSync
NEC Multisync
Princeton

Backup Power Supplies

This article presents some information about backup power supplies.
This article has been archived and is no longer updated by Apple.
Here are a few evaluations done on standby power supplies, which will allow users, should a brownout or power failure occur, to shut down their systems without losing data.

An evaluation in the April 30, 1990, PC Week cited two products:

- SPS300: a 300 volt-ampere device from ITT Powersystems Corp.
- MM300SS: a 312 volt-ampere device from Sutton Designs

Both units kept the PC Week system operating for 12 minutes after a power outage.

An evaluation in the February 12, 1990 Infoworld mentioned the following products:

- 600-LS: a 600 volt-ampere device from American Power Conversion Corp.
- Linebacker 300: a 300 volt-ampere device from SL Waber, Inc.
- 650FR: a 650 volt-ampere device from Alpha Technologies, Inc.

An evaluation in the April 1989 Byte magazine discussed the following:

- VIP 800: a 800 volt-ampere device from ITT Powersystems Corp. that gave a 10-minute reprieve after a power failure.
- PC/ET: a 360 volt-ampere device from Emerson Electric

For more information, search the Web using the company names.

Macintosh IIci, IIfx, IIsi, LC: Memory Manager Performance

A customer reported that a Macintosh IIfx took 12-13 minutes to load and display an Adobe PhotoShop file. A Macintosh IIx took 1-2 minutes to load and display the same file. The customer was not using the black terminator, or the internal SCSI filter on the Macintosh IIfx. After the customer installed these, the Macintosh IIfx performed as expected.

This article has been archived and is no longer updated by Apple.
There is a minor problem in the Memory Manager in the ROMs of the Macintosh IIci, IIfx, IIsi, and LC. This results in performance degradation in an extremely small number of applications, and doesn't cause system crashes. This affects few applications and very few customers. It is not a new problem and it only applies if you're using System 6, System 7.0 corrects this bug.

During extensive testing and research, Apple investigated a variety of solutions to enhance the memory manager performance. One solution was software called the Memory Manager INIT (a software "patch"). Testing revealed that this patch did not enhance Memory Manager performance, and introduced risks, such as decreased performance, in some mainstream applications. We are aware of the distribution of an unofficial version of the Memory Manager INIT. This INIT was modified from Apple's experimental version, and should NOT be used. This INIT can cause data corruption, data loss and system crashes. Apple strongly urges that you throw away this INIT.

Because of the minimal impact, the Apple task force decided that it was not necessary to develop, test, and release a patch to the Memory Manager for System 6. It is important to realize the implications of patching the Memory Manager. Since it is at the heart of everything the Macintosh does, any patch would require major testing resources to cover the entire product line, large numbers of applications, and Network and Communications products.

Based on developer feedback, customer feedback, and extensive in-house testing, Apple identified very few affected applications.

If you have a customer reporting slow downs on the Macintosh IIci, IIfx, IIsi, or LC, check the following items:

1) They aren't using built-in video. The Macintosh IIci and IIsi cycle-steal. The LC does not.

2) They have a clean System folder. Large numbers of INITS cause many problems.

3) They don't have network-based problems that also cause slow downs.

4) They have a properly configured SCSI bus.

5) They generally have a configuration that works.

If the slow performance persists after checking these items, it may be due to a Memory Manager software problem. The best solution would be to upgrade to System 7.

Macintosh: Plotter Driver Software

Plottergeist is a Macintosh Chooser-level plotter driver that supports Hewlett-Packard and Houston Instrument plotters.
This article has been archived and is no longer updated by Apple.
Plottergeist, from Palomar Software, allows the connection of a Macintosh to plotters to produce plotted output from CAD software, presentation packages, drawing and graphics programs. Compatible with all Macintosh applications, the plotter can be chosen from within a software application.

Background printing allows users to work on the Macintosh while their document is being plotted. A preview mode allows users to see their entire document before sending it to be plotted.

Arbitrary reduction and enlargement allows scaling output to fit from a standard letter-size page to a 36 by 48-inch E-size drawing. You can print smooth text in large sizes, or use the plotter's built-in fonts for fast draft work.

The package includes disk, manual and an RS-232 interface cable.

Plottergeist requires a Macintosh Plus or later. Background printing requires 2MB of RAM and MultiFinder.

Macintosh: Connections Software from Concentrix

This article describes Connections¬ software for the Macintosh.

This article has been archived and is no longer updated by Apple.
Connections software, from Concentrix Technology, Inc. consists of applications such as personal calendaring, to-do lists, a telephone directory, call tracker, daily accomplishments journal, and text information organizer. It provides an interface to IBM PROFS electronic mail and group calendaring.

Many of the functions of PROFS calendaring and electronic mail can be done off line, including archiving, organizing, and searching e-mail messages. If the mainframe or network goes down, the user still has access to the calendar and previously read e-mail messages. Mail messages can also be created off line and sent from Connections' out basket.

Connections offers slots for additional modules that can be created with other third-party connectivity tools, such as MitemView or SQL/DAL add-ons.

Connections can be modified in HyperCard.

The address and phone number of Concentrix Technology, Inc. are in a separate article in the Tech Info Library.

Personal LaserWriter NT: Switch Settings

Users sometimes confuse the Personal LaserWriter NT switch assembly with the SCSI ID selector found on SCSI hard drives. These users change the printer mode number from zero (the default LocalTalk/PostScript setting) to another number. If the printer is set to anything other than zero or seven, the printer will disappear from the Chooser and the green ready light may begin blinking. How can users resolve this problem?
This article has been archived and is no longer updated by Apple.
To resolve this problem, reset the mode selector switch to zero, then restart the printer. When the test page prints, verify that it contains the desired printer configuration information.

The Personal LaserWriter NT has two connectors (DIN-8, DB-25) and a switch assembly that looks almost identical to the SCSI ID selector switch on external SCSI drives. The switch assembly sets the printer mode (LocalTalk/PostScript, Diablo 630 Emulation, and so on) for the printer, and has nothing to do with a SCSI ID setting.

Switch setting information:

Switch	Port	Mode Setting
0	Din-8	AppleTalk, PostScript (normal mode)
	DB-25	Serial, no input
1	Din-8	Serial (9600), (No parity), 7 data bits, 1 stop bit, XON/XOFF, PostScript Batch Mode
	DB-25	Serial 9600, No parity, 7 data bits,1 stop bit, XON/XOFF, PostScript Batch Mode
2	Din-8	Serial 9600, No parity, 8 data bits, 1 stop bit, XON/XOFF, HP Emulation
	DB-25	Serial 9600, No parity, 8 data bits, 1 stop bit, XON/XOFF, HP Emulation
3	Din-8	Serial 9600, No parity, 8 data bits, 1 stop bit, XON/XOFF, Diablo 630 Emulation
	DB-25	Serial 9600, No parity, 8 data bits, 1 stop bit, XON/XOFF, Diablo 630 Emulation
4	Din-8	Serial 1200, No parity, 7 data bits, 1 stop bit, XON/XOFF, PostScript Batch Mode
	DB-25	Serial 1200, No parity, 7 data bits, 1 stop bit, XON/XOFF, PostScript Batch Mode
5	Din-8	Serial 9600, No parity, 8 data bits, 1 stop bit, no handshake(?), PostScript Batch Mode
	DB-25	Serial 9600, No parity, 8 data bits, 1 stop bit, DTR, PostScript Batch Mode
6	Din-8	Serial 9600, No parity, 8 data bits, 1 stop bit, XON/XOFF, PostScript Binary Mode
	DB-25	Serial 9600, No parity, 8 data bits, 1 stop bit, XON/XOFF, PostScript Binary Mode
7	Din-8	AppleTalk, PostScript (normal mode)
	DB-25	No input

Notes:
- For switch positions 1 through 6, the parameters are listed in the following order: data transfer rate, parity check, number of data bits, stop bits, handshake and mode.

- PostScript Binary Mode allows the user to change in and out of the various emulation modes (like Diablo 630 and HP Emulation) while still in PostScript by using control codes. This was a limiting factor on the LaserWriter IINTX, but is available on the Personal LaserWriter.

- When the switch is set to 4 and you turn on the printer, you will get a diagnostic page instead of the normal startup page. This page shows the current parameters of each switch setting and other useful information.

- To Connect the Personal LaserWriter to an MS-DOS computer with a LocalTalk PC Card installed, use setting 0 or 7 [0 is the default setting from the factory].

Apple II High Speed SCSI Card: CMS Hard Drive (11/96)

My computer does not recognize a CMS hard drive when using the Apple II High Speed SCSI card. How can I correct this problem?

This article has been archived and is no longer updated by Apple.

Ensure DIP switch 8 on the CMS hard drive is in the closed position. DIP switch 8 controls the reset line at pin 40. All Apple SCSI cards use the reset line for handshaking. If this pin is disconnected or turned off, the computer will not recognize the hard drive.

If your computer still doesn't recognize the CMS hard drive, check the SCSI switch to make sure it is not set to 7.

Apple IIGS: Remove AppleTalk Before Internal Test

I performed an internal test on my Apple IIGS using the Command-Control-Option-Reset key sequence. Soon after I did this, other computers were disconnected from the network. Did my Apple IIGS internal test cause the problem?

This article has been archived and is no longer updated by Apple.
Yes. When performing an internal test on an Apple IIGS that is on an AppleShare network, be sure to disconnect the network connector. Failure to do so will cause severe communication problems with other nodes, and will usually result in other computers becoming electronically disconnected from the network.

Macintosh IIfx: StarController Incompatibility, Workaround

This article describes workarounds for the StarController compatibility problem with the Macintosh IIfx.

This article has been archived and is no longer updated by Apple.
The Macintosh IIfx, with it's new high speed serial ports, has some problems with the "Black Beauty" StarController¬ hub (PN207). If you set the serial ports on the Macintosh IIfx to "Compatible Mode" everything works fine. But in "High Speed Mode," network performance actually drops if you are going through a StarController.

The problem involves the StarController timing PAL (a socketed programmable analog logic chip) and the way AppleTalk is implemented on the Macintosh IIfx. By replacing the PAL with a GAL (gate array logic chip), you can restore StarController and Macintosh IIfx communication.

The StarController Series 300 hub, which replaces Black Beauty, works fine with the Macintosh IIfx in "High Speed Mode." If you have a Black Beauty StarController and want the PALs replaced by GALs, you can get an upgrade kit, available to the general public (U.S. ONLY).

The address and phone number for Farallon is in a separate article in the Tech Info Library.

Macintosh IIfx: Logic Board Jumper Settings

A customer's Macintosh IIfx is not functioning, and I suspect that the jumper settings on the logic board have been altered. What should I check for?

This article has been archived and is no longer updated by Apple.

Jumper J103 on the Macintosh IIfx logic board disables the external 68030 RAM cache when it is disconnected. In the event that the jumper is removed, the system may not reset properly when turned on, essentially disabling the system.

As a side note, the jumper next to J103, J106, is used for debugging. This jumper is not documented because it can severely affect system performance.

Data Modem 2400: Reset Parameters Before Testing

My customer is unable to establish communications with a dial-up service or another modem. The modem dials out, but as soon as the connection with the other modem is made, it hangs up. The Apple ModemTest diagnostic confirms a failure in the modem board. Since replacing the main board doesn't solve the problem, what should I do next?

This article has been archived and is no longer updated by Apple.
The Data Modem 2400 has many parameters that are configured through software. Some of the finished goods units, and some of the service stock boards, may not be configured for normal use. The current ModemTest diagnostic test will fail any modem that has parameters other than the default settings.

Reset the modem parameters to the default settings. Do this by pressing the switch on the front of the modem while turning it on, or by issuing the 'AT&F' command using a terminal emulation package. The reset procedures are documented in the owner's guide.

Logo: Disk Replacement

Is it still possible to get a replacement for bad Logo disks?
This article has been archived and is no longer updated by Apple.
Yes. Logo Computer Systems, Inc. still supports Logo purchasers with replacement disks as needed. There is a charge for replacement, and you must send them the damaged disk.

If you call the Montreal number, and don't understand French, the electronic message will switch over to English if you wait a while.

Search the Tech Info Library for a separate article that gives the phone number and address for Logo Computer Systems, Inc.

Macintosh Portable: Battery Recharger

This article describes battery rechargers for the Macintosh Portable.

This article has been archived and is no longer updated by Apple.
Apple Computer sells the Macintosh Portable Battery Recharger (p/n M0275). It comes with a power adapter and a cradle that holds the battery while it is recharging.

Lind Electronic Design, Inc. (LED) markets a specially designed External Battery Charger for the Macintosh Portable Rechargeable Battery. It comes in a molded plastic box with carrying handle. It measures 3.3 x 6 x 7 inches, weighs 1.6 lbs. without the spare battery, and obtains power through Apple's Power Adapter from a 115V AC wall outlet. It can also charge the battery from a 12V DC power source such as a vehicle cigarette lighter.

LED also sells a 12V DC Automobile Power Adapter that plugs into the Macintosh Portable through the Power Adapter port. The Automobile Power Adapter can operate the computer and charge its internal battery from a 12V DC power source. A regulator prevents the Power Adapter from overcharging the Macintosh Portable's internal battery. It weighs only 0.75 lbs, measures 1.9 x 2.4 x 3.3 inches, and comes equipped with a Velcro fastener strip to attach it to the side of the Macintosh Portable's case. When the Adapter is not in use, all power cords and plugs fit into the Portable case.

TA46092_InterPoll_The_Role_of_Responder_(TIL07451).pdf

InterPoll: The Role of Responder

Article Change History

08/21/92 - EDITED
* For clarity and technical accuracy.

What is Responder?

This article has been archived and is no longer updated by Apple.
Responder is a resource placed in individual Macintoshes that identifies that computer - and any others in the network that have Responder installed - when the Inter*Poll program runs. At startup time, Responder reads the name of the user and the Macintosh name where it resides, then the versions of the system software, LaserWriter driver, and AppleTalk. Inter*Poll requests this information later to tell the system administrator the characteristics of the user's system. Inter*Poll interrogates each system, and Responder answers Inter*Poll.

LocalTalk Interface Board from DayStar Digital

This article describes the LocalTalk Interface Board manufactured by DayStar Digital, Inc.
This article has been archived and is no longer updated by Apple.
The LT200 LocalTalk Interface Board allows IBM PC, PS/2, and Macintosh computers to coexist on a LocalTalk network. The LT200 is a card that fits into the expansion slot of a PC or PS/2. Users can plug directly into the LocalTalk network and have access to LaserWriters, Macintosh computers and other devices on the network.

The LT200 includes printer utilities that allow PCs to print to PostScript printers.

This article provides information about a non-Apple product. Apple Computer, Inc. is not responsible for its content. Please contact the vendor for additional information.

Macintosh II Family: NuBus Video Port Expanders

This article describes NuBus video port expanders for the Macintosh II family, manufactured by Network Technologies, Inc.

This article has been archived and is no longer updated by Apple.

Vopex-2M

The Vopex-2M video port expander allows two Macintosh II monitors to be driven from the same video port. In addition, the operating distance between the Macintosh and its monitors can be extended to 50 feet. This permits the relocation of monitors into classrooms, control rooms, factory floors and applications using video projectors. Vopex-2M has 50 MHz bandwidth and no resolution loss. The Macintosh II interface cable is included.

Vopex-8M

The Vopex-8M is a video port expander for the Macintosh II video standard and is functional with both the monochrome and color monitor. The Vopex-8M allows eight monitors to be driven by a single Macintosh II at distances up to 50 feet from the computer. It is a device for applications such as training rooms, presentations, video printers and video projectors.

The Vopex-8M connects directly to a Macintosh II video port via a 4-foot interface cable supplied by NTI. All eight output ports are individually buffered. The Vopex-8M operates with monochrome or color monitors because it precisely tracks the input signal.

It is easy to install and operates by plugging any compatible Macintosh II monitor directly into the 15-pin D output connectors. Extension cables fitted with the same 15-pin D connectors are available in lengths of 25, 35 and 50 feet.

The Vopex-8M is housed in an 8 by 2.5 by 6.2-inch package and powered by 110 VAC.

For more information, search under "Network Technologies".

HyperCard 1.2.x: System Software Incompatibility

If you are using system software version 6.0.6, 6.0.7, or 7.0 you may have heard that you can't use HyperCard 1.2.2 or 1.2.5. The following discussion tells you how to recover when one of these HyperCard versions causes your computer to lock up.
This article has been archived and is no longer updated by Apple.
HyperCard generates sound when a stack uses play or beep, or makes a sound because you typed a wrong key. With system software version 6.0.6, 6.0.7, or 7.0, HyperCard 1.2.x will lock up when sound is produced for any reason. When this happens, type the Command-Period (Command-.) key sequence. If you were editing a script when the program locked up, the script window closes; if a script was executing, it is canceled.

To prevent HyperCard from causing a lock-up condition, avoid making a sound. Set your Speaker Volume to 0 from the control panel. You won't hear any sounds, but your stack will avoid this sound problem.

If you must play a sound, you can use Farallon's fplay external command (and associated resources) from Farallon's HyperSound¬ Toolkit. If you use HyperSound, substitute fplay for every occurrence of the play command or beep command.

If you don't have to use HyperCard 1.2.x with System 6.0.7 or 7.0, don't use it. If possible use HyperCard 2.0. HyperCard 1.2.x is officially not compatible with System 6.0.7 or 7.0. So you may find problems other than those described above.
Published Date: Feb 18, 2012

AppleTalk: System Errors and Third-Party Software

Some third-party software products cause system crashes when AppleTalk is turned off.

This article has been archived and is no longer updated by Apple.

If AppleTalk is turned off, you may get error codes 3, 10, 12, or 85 while using system software 6.0.5 or higher with network-aware software. Some third-party software products go out and check the network, and if AppleTalk is turned off, the system crashes.

To fix this problem, use the Chooser to make sure AppleTalk is turned on.

Personal LaserWriter LS: Upgrading to 1MB RAM

This article tells you what you need to upgrade a Personal LaserWriter LS to 1MB of RAM.

This article has been archived and is no longer updated by Apple.
The standard amount of RAM in a Personal LaserWriter LS is 512K. The speed of this RAM is 100ns.

To upgrade to 1MB, you need four 256K x 4-bit 100ns RAM chips. Third-party companies supply this memory. Note that this is NOT 256K x 1-bit memory, which the Apple IIGS uses.

Published Date: Feb 18, 2012

Macintosh IIsi and LC: Third-Party SIMM Incompatibility

Some Macintosh IIsi and Macintosh LC customers have difficulties with third-party 2MB SIMMs installed in their systems. Reported problems include system hanging and/or system crashes sometime after a third-party 2MB SIMMs upgrade. Read the following discussion for more details.

This article has been archived and is no longer updated by Apple.
Apple investigated the problem and discovered that this occurs because some third-party 2MB SIMMs are not compatible with the Macintosh IIsi and the Macintosh LC.

You can determine whether your third-party 2MB SIMMs are compatible with a Macintosh IIsi or Macintosh LC by removing them from the system and installing known good Apple 1MB SIMMs. If the symptoms disappear, the problem was in the third-party SIMMs, and you should discontinue using them in your system.

Contact the manufacturer of the third-party SIMMs if this troubleshooting procedure determines they are incompatible.

Laser Printers: Ozone Emissions

This article provides guidelines for reducing ozone emissions from laser printers, as well as suggestions for minimizing the effects of ozone in the workplace.
This article has been archived and is no longer updated by Apple.
Apple Computer has prepared this document to help answer questions about ozone emissions from laser printers. We have used information from the American Conference of Governmental Industrial Hygienists (ACGIH), the National Institute for Occupational Safety and Health (NIOSH), the Occupational Safety and Health Administration (OSHA), and the Underwriters Laboratory (UL). For additional assistance please contact an authorized Apple reseller or call Apple Customer Relations at 1-800-776-2333. To locate an Apple reseller in your area, call 1-800-538-9696.

Background Information

Ozone gas is emitted in detectable levels by some laser printers and photocopiers as a byproduct of the electrophotographic process. In laser printers the primary source of ozone is the corona wire which produces an electrical discharge to make the toner powder temporarily adhere to the print drum.

Ozone is produced only when the printer is printing. The current OSHA permissible exposure limit for ozone is 0.1 parts of ozone per million parts of air (ppm) averaged over an 8-hour work shift.

Manufacturers install special filters to ensure safe ozone emission levels. Laser printers that operate without a corona wire emit a negligible amount of ozone gas and do not require these filters. In the US, UL provides an ozone emission standard based on OSHA exposure limits. In Europe, the maximum permitted ozone concentration is specified by European Norm (EN).

A properly maintained laser printer that is installed in a well-ventilated area should not expose users to unsafe ozone levels. In general, filter effectiveness can diminish in direct proportion to the number of pages printed. Therefore, filters should be replaced periodically. Dust accumulating on the filter's surface can also affect its performance.

Ozone can be a mild to severe irritant (dry throat and nose, headache, and sore eyes) and at very high concentrations can have serious adverse health effects such as nausea and pulmonary congestion.

Ozone (O_3) is a highly unstable molecule that reverts quickly to oxygen (O_2). Ozone concentrations may rise to noticeable levels depending on the rate generated (amount and time) as well as the physical environment (such as room ventilation and location of workers).

Typically, ozone can be identified by its characteristic odor at concentrations below the permissible exposure limit. However, as the concentration of ozone or the duration of exposure increases, the ability of a person to smell it may decrease.

Apple's LaserWriter Printers

Apple is committed to making products that meet or exceed the industry and government health and safety guidelines of every country where we do business. All Apple laser printers are within the limits of the UL guidelines when shipped from the factory to the customer. The technology is advancing, however, and most new laser printers have no corona wire and do not emit ozone.

Of Apple's printer products, only the Color LaserWriter 12/600 PS and the Color LaserWriter 12/660 PS have corona wires. These printers have ozone filters that are designed to operate effectively for printing up to 100,000 pages. For maximum effectiveness, Apple recommends service (checking the entire ozone emission control system) and an ozone filter replacement after 50,000 pages. You can print a startup page to determine your laser printer's page count. Dusty conditions or damage to the filter may necessitate more frequent filter replacement. This maintenance check and filter replacement can be done by any authorized Apple service provider.

The laser printer works best in relative humidity between 30 and 70 percent. Lower humidity can slow the natural breakdown of ozone in the air and can reduce the filter's effectiveness.

Proper installation of your laser printer will help to keep the ozone concentrations at a safe level. Choose a well-ventilated area. In general, a correctly designed air-conditioning system provides adequate ventilation for printer use. Air circulation is especially important if there are multiple laser printers and/or photocopy machines in an area. A small, enclosed space such as a closet should not be used for printing. Placement in a common area is preferable to placement in an individual's workspace. The fan exhaust should not blow directly in anyone's face.

None of Apple's other printers emit ozone. The ImageWriter II; Color StyleWriter 1500, 2200, 2400, 2500 & Pro, and Apple StyleWriter 1200 are not laser printers and do not emit ozone. The Personal LaserWriter 300 & 320; LaserWriter 4/600 PS, 16/600 PS & 12/640 PS; and LaserWriter Select 360 do not have a corona wire and therefore do not require an ozone filter in order to meet UL safety requirements.

StyleWriter: Clear the Ink Cartridge When Installing a New One

When installing a new ink cartridge in the StyleWriter printer, you must clear the cartridge. This process, which takes several seconds, is detailed in the StyleWriter User's Manual:

This article has been archived and is no longer updated by Apple.
Here's how to do it:

1) Turn the StyleWriter's Power Switch off.

2) Press the Ready switch (located on the left) and hold.

3) Press the Power switch (located on the right) and release both switches simultaneously.

Do all this twice. You may hear some whirring and clicking sounds as the cartridge is cleaned, but consider it a normal part of the process.

Published Date: Feb 18, 2012

StyleWriter: Protect Ink Cartridge during Air Transport

Low air pressure during air transport can cause ink to pump from the StyleWriter cartridge.

This article has been archived and is no longer updated by Apple.
When transporting a StyleWriter printer by air, always remove the cartridge from the printer and then protect it.

The best solution is to carry a new cartridge still in its plastic carton.

To provide minimum protection, place the opened cartridge in a sealed plastic bag.

Macintosh LC Apple IIe Card version 1.0: Software Compatibility

Apple makes no warranty or representation, either expressed or implied, with respect to this list, its quality, accuracy, or fitness for a particular purpose. In no event will Apple be liable for direct, indirect, special, incidental, or consequential damages resulting from any defect or inaccuracy in this list. Please contact the developer for current compatibility information.

Mention in this list does not constitute an endorsement by Apple Computer, Inc. Third-party product information is provided for compatibility reasons only.

Please contact your dealer or the software developer if you have any questions. They can help you identify the newest version of a particular program or tell you how to upgrade your current version if necessary. For best results, we recommend you use the latest versions of software and hardware products with your Apple IIe Card for the Macintosh LC.

TA46109_Lisa_Pascal_CRUNCH_(TIL00748).pdf

Lisa Pascal: CRUNCH

This article has been archived and is no longer updated by Apple.
Page 10-6 Pascal Language Manual indicates that a file closed with CRUNCH should move the EOF mark to the last place of access. This is not the case. If this function is important to users, they may need to write their own routines, insert their own EOF character, or possibly maintain an EOF pointer, which would suggest using block I/O.

Personal LaserWriter LS, StyleWriter: Software Compatibility

The following list is a compatibility report on the Personal LaserWriter LS, StyleWriter, and TrueType INIT. These are the findings as of February 26, 1991.

Even though Apple has reviewed this list, Apple makes no warranty or representation, either expressed or implied, with respect to this list, its quality, accuracy, or fitness for a particular purpose. In no event will Apple be liable for direct, indirect, special, incidental, or consequential damages resulting from any defect or inaccuracy in this list. Please contact the developer for current compatibility information.

Mention in this list does not constitute an endorsement by Apple Computer, Inc. Third-party product information is provided for compatibility reasons only.

DISCUSSION----------

4th Dimension 2.11 - No problem.
Acta 3.01 DA - No problem.
Adobe Illustrator 88 1.9.3 - TrueType problems with text in large point sizes. TrueType quality will not be very high in any point size. Adobe Illustrator 3.0 - Requires Adobe Type Manager 2.0, does not take advantage of TrueType. Prints to Personal LaserWriter LS at 72 DPI.
Adobe Photoshop 1.0 - No problem.
Adobe Type Manager 1.2 - No problem.
Adobe Type Manager 2.0 - No problem.
Aldus Freehand 2.02 - On Personal LaserWriter LS, may experience crashes when printing graphics which were created as bitmaps in another application and then pasted into Freehand through the clipboard.
The StyleWriter has the following problems: Some features do not work correctly. Lines assigned a width of 0 should print as hairlines, but are printed as 1 point lines. Some rounded rectangles do not print as smoothly as other printers.
AppleScan 1.02 - No problem.
atOnce! 1.01 - No problem.
Canvas 2.1 - No problem.
Claris CAD 1.0v5 - No problem.
Color Studio 1.0 - No problem.
Cricket Draw 1.1.1 - No problem.
Cricket Graph 1.3 - Does not display third-party TrueType fonts.
Cricket Paint 1.0 - No problem.
Cricket Presents 2.0.1 - Times Bold/Italic lines of text sometimes get cut off when printing Personal LaserWriter LS.
Delta Graph 1.5 - No problem.
Design Studio 1.01 - No problem.
Digital Darkroom 1.1a - When printing a select portion of a document to a StyleWriter from a Macintosh SE, the system will crash. Printing a Digital Darkroom document to the StyleWriter, the image is recreated eight times in miniature at the top of the page. A black line appears across the print options box of the StyleWriter driver.
Dreams 1.1 - TrueType text occasionally causes a Personal LaserWriter NT to crash. Printing rotated text to the Personal LaserWriter LS, both the rotated object and the original non-rotated object are printed.
FoxBASE+/Mac 2.01 - TrueType fonts with bitmaps installed have spacing problems when printed, and bottoms of characters are sometimes clipped.
FileMaker II 1.1v2 - No problem.

FileMaker Pro 1.0v1 - No problem.
Full Impact 2.0 - Text is dropped when printing to Personal LaserWriter LS under MultiFinder.
FullWrite Professional 1.1 - No problem.
HyperCard 2.0v2 - No problem.
Image Studio 1.7 - In landscape mode, prints strips of garbage across the page. Happens to a number of printers, including Personal LaserWriter LS and StyleWriter.
LetraStudio 1.5 - Designed only for Letraset's proprietary or Postscript fonts, will not benefit TrueType users.
MacDraft 2.0 - No problem.
MacDraw 1.9.8 - No problem.
MacDraw II 1.1v2 - No problem.
MacWrite II 1.1v1 - Type sizes greater than 127 will not display or print correctly. TrueType fonts will not display correctly in reduced view.
MacFlow 3.0.3 - No problem.
MacInTax 89 2.0 - No problem.
MacMoney 3.5 - No problem.
MacPaint 2.0 - No problem.
MacProject II 2.0v3 - No problem.
MacroMind Director 2.0 - No problem.
MacWrite 5.0.1 - No problem.
Microsoft Excel 2.2a - No problem.
Microsoft PowerPoint 2.01D - TrueType text spacing is bad enough to cause the text to be illegible on the Macintosh II family of CPUs. This problem does not occur with PowerPoint 2.01.
Microsoft Word 4.0b - When printing to the Personal LaserWriter SC or LS, TrueType output sometimes has line breaks in the wrong places, and incorrectly spaced characters.
Microsoft Works 2.0b - No problem.
MiniCad+ 2.0v6 - Double underlines print as single underline on the Personal LaserWriter LS and StyleWriter. StyleWriter drops all underlines at 40% reduction.
More 3.0 - No problem.
Nisus 2.11 - No problem.
Nisus 3.01 - No problem.
PageMaker 3.02 - No problem.
PageMaker 4.0 - No problem.
Persuasion 2.0 - No problem.
PixelPaint Professional 1.0.1 - Printing to Personal LaserWriter LS and StyleWriter often causes a crash.
Quark XPress 2.12 and 3.0 - Problems with large point sizes and reduced and enlarged view.
Quickmail 2.2.3 - Will not print in text mode to the StyleWriter.
Quicken 1.5 - No problem.
ReadySetGo 4.5 - No problem.
ReadySetShow 1.0 - No problem.
SmartForm Assistant/Designer 1.1v1 - Place rotated text on mailing labels template does not print onto every label when printing to Personal LaserWriter LS and StyleWriter.
Statview SE+ Graphics 1.03 - No problem.
Studio 1 1.0 - No problem.
Studio 8 1.1 - No problem.
SuperCard 1.5 - No problem.
SuperPaint 2.0a - When printing complicated text and graphics to the Personal LaserWriter LS, some objects do not print.
UltraPaint 1.02 - No problem.
Vellum 1.0 - No problem.
WingZ 1.1 - When "center" page setup option is selected, extra blank pages are printed out to the Personal LaserWriter SC and LS.
WordPerfect 1.0.5 - No problem.
WriteNow 2.2 - When printing to the StyleWriter, occasionally characters

overlap.

?END7505

Do I really need CD Remote DA in my System Folder?

This article has been archived and is no longer updated by Apple.
You need the CD Remote DA only if you are playing audio CDs. It is not needed for using CD-ROMs.

Published Date: Feb 18, 2012

System 7: Memory Requirements

Article Change History

09/17/92 - REVISED
* To set 2MB capabilities more realistically.

The following information provides guidelines for memory (RAM) usage with System 7.

This article has been archived and is no longer updated by Apple.
The minimum requirement to run System 7 is a 2MB system with a hard disk. User testing shows that this configuration is functionally equivalent to a 1MB configuration running system 6.0.7. But to take full advantage of System 7 and multiple and/or larger applications you will need at least 4MB of RAM.

Here is a rough guide to memory usage:

* 1MB - Use system 6 with one application.

* 2MB - Use System 7, the Finder, and one application.

* 2.5MB - Use System 7, the Finder, and one or two applications.

* 3MB to 5MB - Use System 7, the Finder, and multiple applications or one large application.

* 5MB to 8MB - Use System 7, the Finder, and multiple large applications and/or documents.

Because of System 7's built-in multitasking, users may launch a second application without quitting from the first. In a 2MB system, this will frequently produce an "Out of Memory" error message. To avoid these messages, users with 2MB Macintosh computers should quit each application before using another. This will not affect their ability to use the multitasking features of System 7, such as background printing and file copying.

System 7 consumes 500K to 1MB more memory than system software 6.0.x. Consider adding one to two megabytes of memory to a Macintosh with limited memory. Or use System 7's virtual memory feature, which is available on the Macintosh SE/30, IIx, IIcx, IIci, IIfx, and Macintosh II with optional PMMU.

Because of differences in system ROMs and video architecture, each Macintosh configuration has slightly different system memory usage under System 7. Here are the basic memory profiles of System 7 on various Macintosh computers, using basic install with file sharing and program linking turned off:

	Memory Consumed	Memory Free*
Macintosh Plus	1056K	992K
Macintosh SE	1125K	923K
Macintosh SE/30	1271K	777K
Macintosh Portable	1085K	963K
Macintosh Classic	1123K	925K
Macintosh LC	1298K	750K
Macintosh IIsi	1216K**	1085K***
Macintosh II	1275K	773K

Macintosh IIx 1268K 780K
Macintosh IIcx 1298K** 750K
Macintosh IIci 1202K 796K
Macintosh IIfx 1185K 2911K****

* Available application memory in a 2MB configuration. Any memory above 2MB is available for application use as well.
** 8-bit color video consumes an additional 280K.
*** 3MB configuration
**** 4MB configuration

Note: Macintosh file sharing consumes an additional 260K.

Published Date: Feb 18, 2012

Applesoft Internals: Floating Point Math Package (2 of 2)

Applesoft's floating point package provides a 9 digit scientific package for evaluating numeric equations. It supports trigonometric functions with arguments in radians, exponents and logarithms to base e.
This article has been archived and is no longer updated by Apple.

TRANSCENDENTAL OPERATORS

FPWRT EE97
Raise ARG to the FAC power. On entry A and Z must reflect the value of FACEXP.

SQR EE8D
Takes the square root of FAC

LOG E941
Log base e of FAC

EXP EF09
Raise e to the FAC power

COS EFEA
Returns the cosine of the FAC in radians.

SIN EFF1
Returns the sine of the FAC in radians.

TAN F03A
Returns the tangent of the FAC in radians.

ATN F09E
Returns the inverse-tangent of the FAC in radians.

OTHER OPERATORS

SGN EB90
Modifies the value of the FAC depending on its value on entry.
On exit:
FAC = 1 if FAC was greater than 0
FAC = 0 if FAC was equal to 0
FAC = -1 if FAC was less than 0

ABS EBAF
Absolute value of FAC. If FAC is less than 0 then FAC = -FAC.

INT EC23
Greatest integer value of FAC. Uses QINT and floats the result.

RND EFAE
Form a pseudo-random number in FAC and update RND at 00C9.

SIGN EB82
Set A according to the value of FAC.
On exit:
A = 1 if FAC is positive
A = 0 if FAC = 0
A = FF if FAC is negative

FCOMP EBB2
Compare FAC and a packed number in memory pointed to by Y,A.
On exit:
A = 1 if (Y,A) < FAC
A = 0 if (Y,A) = FAC
A = FF if (Y,A) > FAC

NEGOP EED0
FAC = -FAC

FADDH E7A0
Add 1/2 to FAC

DIV10 EA55
Divide FAC by 10. Returns positive numbers only.

MUL10 EA39
Multiply FAC by 10. Works for both positive and negative numbers.

LOWER LEVEL INTERFACE ROUTINES

FOUT ED34
FOUT creates an ASCII string in FBUFFR equivalent to the value of FAC. On exit Y,A points to the string, which ends with an ASCII null. FAC is scrambled. Use STROUT to print the number.

SNGFLT E301
SNGFLT converts the unsigned number in Y to a floating point number in FAC.

GIVAYF E2F2
GIVAYF converts the unsigned number in Y,A to a floating point number in FAC.

FLOAT EB93
FLOAT converts the signed number in A to a floating point number in FAC.

CONINT E6FB
CONINT converts FAC into a single byte integer in X and FACLO. CONINT normally exits through CHRGET unless FAC is greater than 255 or less than 0, when it exits via ILLEGAL QUANTITY ERROR.

AYINT E10C
If FAC is less than +32767 and greater than -32767, then execute QINT. Otherwise AYINT exits via ILLEGAL QUANTITY ERROR.

QINT EBF2
Quick greatest integer function. Leaves INT(FAC) in FACHO,MO,LO signed. QINT assumes that the absolute value of the FAC is less than 8388608 (2^23rd power).

GETADR E752
GETADR converts the number in FAC to a 2 byte, unsigned integer in LINNUM. When FAC is greater than 65535 or less than -65535, GETADR exits via ILLEGAL QUANTITY ERROR.

GETNUM E746
GETNUM fetches a 2 byte number, a comma and an unsigned, single byte number from TXTPTR. The first number is stored in LINNUM, while the second is returned to the X register. On entry TXTPTR points to the first character of the formula for the first number. GETNUM uses FRNUM, GETADR, CHKCOM and GETBYT.

COMBYTE E74C
COMBYTE checks for a comma, then fetches an unsigned, single byte number returned in X. On entry TXTPTR points to the comma. COMBYTE uses CHKCOM and GETBYT.

FRMEVL DD7B
FRMEVL evaluates the formula at TXTPTR using CHRGET, then leaves the result in FAC. On entry, TXTPTR points to the first character of the formula, while on exit points to the terminator. "A" does not contain the terminator. The format of the temporary result on the stack is:

The address of the operator routine.
The floating point temporary result.
The precedence of the operator.

FRMEVL, the main subroutine for the commands that use formulas, works for both strings and numbers. If the formula is a string literal, FRMEVL gobbles the opening quote, then executes STRLIT and ST2TXT.

FRMNUM DD67
FRMNUM evaluates the formula at TXTPTR, puts it in FAC, then makes sure the result is numeric. On entry TXTPTR points to the first

character of the formula. FRMNUM exits through TYPE MISMATCH ERROR if the result is a string.

FIN EC4A

FIN inputs a floating point number into FAC from CHRGET. FIN assumes the 6502 registers and A were set up by the CHRGET that fetched the first digit. FIN only operates on numeric constants, not formulas.

QuickTime Streaming Server 2.0: Compatible File Formats

This article describes the file formats compatible with QuickTime Streaming Server 2.0.

Notes:

1. All information in this article comes from the help file distributed with QuickTime Streaming Server 2.0. The help file includes additional help topics which are not covered in the Knowledge Base.

2. This article discusses software for use only with Mac OS X Server version 1.2, released prior to May 2001.

This article has been archived and is no longer updated by Apple.

Compatible File Formats

You can stream these media files using QuickTime Streaming Server, as long as the media is hinted:

Category	Formats
Video	QuickTime
	AVI
Audio	AIFF/AIFC
	SoundDesigner II (SDII)
	System 7 Sound
	uLaw (AU)
	WAV
MIDI	Karaoke MIDI
	Standard MIDI

Media File can be compressed using these methods:

Category	Compression-Decompression Method (CODEC)
Preferred Video	Sorenson Video
	H.263
	Motion JPEG A
	H.261
Supported Video	Animation
	Cinepak
	Graphics
	Motion JPEG A
	Photo JPEG
	Video
	None
Preferred Audio	QDesign Music codec
	QUALCOMM Pure Voice
	DVI 4:1
	ALaw 2:1
	uLaw 2:1
	16-bit raw
Supported Audio	IMA 4:1
	MACE 3:1
	MACE 6:1

Published Date: Feb 18, 2012

QuickTime Streaming Server 2.0: What‘s New in Version 2.0

This article describes new features in the QuickTime Streaming Server verwsion 2.0.

Notes:

1. All information in this article comes from the help file distributed with QuickTime Streaming Server 2.0. The help file includes additional help topics which are not covered in the Knowledge Base.

2. This article discusses software for use only with Mac OS X Server version 1.2, released prior to May 2001.

This article has been archived and is no longer updated by Apple.

What's New in QuickTime Streaming Server

- Accessibility. You can stream media using RTP and RTSP over HTTP. This means users can view media through most firewalls.
- Relay support. You can replicate content for live broadcasts. With relays, you can scale streaming services to reach more viewers.
- Enhanced logging. QuickTime Streaming Server software now supports third-party analysis tools that provide consolidated server reporting.
- Authentication support. You can control access to media files using the Authentication modules that come with QuickTime Streaming Server software, or you can supply your own module.

For more information about QuickTime Streaming Server, see these web sites:

- QuickTime Streaming Server: **http://www.apple.com/macosx/server/**
- QuickTime: **http://www.apple.com/quicktime/**

QuickTime Streaming Server 2.0: Use only Playlist Broadcaster 2.0

I just upgraded to QuickTime Streaming Server 2. Can I use PlaylistBroadcaster 1.02 with it?

Note: This article discusses software for use only with Mac OS X Server version 1.2, released prior to May 2001.

This article has been archived and is no longer updated by Apple.
PlaylistBroadcaster 2.0 must be used with QuickTime Streaming Server 2.0. You may lose audio or video performance if you use PlaylistBroadcaster 1.02 with QuickTime Streaming Server 2.0. However, if you are using QuickTime Streaming Server 1.02, you can use PlaylistBroadcaster 2.0.

QTSS 2 is a free update available from the Apple Software Updates Web site at http://www.apple.com/swupdates.

Published Date: Feb 18, 2012

System 7: Virex Compatibility

Is the Virex INIT compatible with System 7? Some customers experience printer errors when printing from a system with the Virex INIT v.3.1 loaded. The compatibility reports say it's compatible, but disabling the INIT corrects the problem.

This article has been archived and is no longer updated by Apple.

The Virex program is compatible with System 7, but the Virex INIT is not fully compatible. Note that at least version 3.5 is available, with improved compatibility. Check with Relay Technology (formely Microcom) for the latest information. Here is Relay Technology's (formely Microcom) recommended workaround:

1) Disable checking on file opening. Checking at disk insertion should work fine.

2) Put the Virex INIT in the root level of the System Folder. Create an alias for the INIT, and place it in the Control Panels folder.

Article Change History
23 July 1993 - Company title changed from Microcom to Relay Technology.
2 September 1992 - Updated, to note that at least version 3.5 of Virex is available.

AppleShare PC 2.0.X Requires AppleTalk Phase 2

Article Change History

08/21/92 - REVIEWED
* For technical accuracy.

I am running AppleShare PC 2.0.1 and a 3Com Etherlink II Board (ThinWire) on an AST 486. When I load ABOTH, I can only see Phase 2 Zones, because our K-Boxes are filtering out Phase 2 traffic. Is there any way I can see our Phase 1 zones the same way I can on my Macintosh using the old EtherTalk Phase 1 drivers? I don't know when we plan to migrate to Phase 2.

This article has been archived and is no longer updated by Apple.
You need AppleTalk Phase 2 for AppleShare PC 2.0 environments using Ethernet or Token Ring networks. If you could attach to a LocalTalk network, then you could use Phase 1. Otherwise, upgrade your present network to Phase 2 as soon as possible.

TA46125_ImageWriter_II_Color_Printing_Applications_(TIL07506).pdf

ImageWriter II: Color Printing Applications

Article Change History

1/15/93 - UPDATED
* Vendor name.

Are there any drivers or programs that print color documents to a ImageWriter II with a color ribbon?

This article has been archived and is no longer updated by Apple.

Most color applications can print in color on an ImageWriter II with the standard driver. These include SuperPaint 2.0 and Cricket Draw.

Silicon Beach Software's (now Aldus Consumer Division) SuperPaint is a graphics editor for bit-mapped (paint) and object-oriented (draw) art. You can toggle between the paint and draw layers by clicking an icon.

Computer Associates International's Cricket Draw is an object-oriented drawing program that can take advantage of the graphics capabilities of PostScript printers (from the LaserWriter to the Linotronic 300). The package consists of two integrated programs: a drawing window and a PostScript language editor. The programs can be used independently or in conjunction.

To locate a vendor's address and phone numbers, use the vendor's name in a search string.

Macintosh Plus: How to Get the "Propeller" Symbol

I want to generate the "propeller" character on my keyboard, but it's produced with the Control-Q key combination, and my Macintosh Plus has no Control key. Is there another way to generate that character directly on the Macintosh Plus?

This article has been archived and is no longer updated by Apple.
We checked through the character sets of all of our fonts and found that symbol only in Chicago under Control-Q. Short of re-defining a font in ResEdit or buying a font-creation product, you can type the character on another Macintosh and save the character in a document that you can transfer (by disk or modem) to your computer. Then, copy the character and paste it into your document.

Apple II: How to Copy Software from 5.25 to 3.5-inch Disks

I want to copy Apple IIe software from 5.25-inch to 3.5-inch disks, using an Apple IIGS--and then run the programs. I get a message that the Apple IIe disk was not formatted in ProDOS. What should I do?

This article has been archived and is no longer updated by Apple.
If the program was written to run under DOS 3.3, it probably won't work under ProDOS. You can use the System Utilities Disk 3.1 to copy the information over to a 3.5-inch disk (the DOS to ProDOS conversion is handled automatically during the copy). However, if the application interacts with the operating system giving DOS 3.3 commands, it won't run. We recommend that you ask the software developer if they have a ProDOS version.

iMovie 2.0.1 Dutch: Command-D Keyboard Shortcut Does Not Work

The Dutch version of iMovie 2.0.1 uses the Command-B keyboard shortcut instead of the usual Command-D for Don't Save.
This article has been archived and is no longer updated by Apple.

Symptom

The keyboard shortcut Command-D does not correspond to the Don't Save button in a Save dialog, which is the common keyboard command for the Don't Save button in the Dutch version of the Mac OS.

Solution

When a Save dialog box appears, use either the keyboard combination Command-B, or click Don't Save.

Apple IIGS: RAM Upgrade, CAS and RAS

I am trying to upgrade an early version of the Apple IIGS and having problems with the 256K chips. Please advise me on the need for CAS and RAS and when and where they are necessary. The solder-in chips on the expansion card don't fall into the category listed in the service manual for replacement. They are NEC/Japan D41256C-15.

This article has been archived and is no longer updated by Apple.
The computer requires CAS before RAS refresh. At one time, we were describing the problem chips, but there are too many different RAM manufacturers. Run the Apple IIGS diagnostic 4.0. You must specifically choose the RAM card test to test the card. If the test comes back with "RAM out of spec," you have the wrong refresh. If the test fails, it is a straight failure. If the test passes, the RAM is the correct refresh and in working order.

Mac OS X 10.0: Can‘t Save to iDisk‘s Software Folder

You cannot save a file to an iDisk's Software folder even though that option is presented in Mac OS X applications.
This article has been archived and is no longer updated by Apple.

Symptom

When saving files from Mac OS X applications, the Software folder of the iDisk is presented as an option. However, when you try to save files to the Software folder an alert with the message "Couldn't Save" appears.

Solution

Use a folder other than the iDisk Software folder. The iDisk Software folder is a read-only folder used by Apple to provide Apple software. It is not possible to save files to the Software Folder.

Mac OS X: .Mac and Internet System Preferences

In order to use .Mac integrated with Mac OS X, the Internet System Preferences must be set up properly.
This article has been archived and is no longer updated by Apple.

Symptom

.Mac will not function properly if the Internet System Preferences are not set up properly.

Solution

Mac OS X contains several features that are tightly integrated with .Mac, Apple's suite of Internet services. To use services such as iDisk access from the Finder, the Internet System Preferences need to be set up properly.

Configuring the Internet System Preferences

1. Open System Preferences.
2. Click Internet to reveal that pane.
3. Click the .Mac tab to select it (unless it is already visible)
4. Enter your .Mac user name and password.

If you do not yet have a .Mac account, either full or trial, you can create one by clicking Sign Up.

Selecting your .Mac email account as your default email account

1. Click the Email tab.
2. Click the checkbox to enable the "Use iTools Email account" feature. The proper email settings are automatically entered into the appropriate boxes.

AppleShare IP 6.3.3: Issues Loading Server Modules

When connecting to an AppleShare IP 6.3.3 Server, an alert box may appear with a message about loading server modules.
This article has been archived and is no longer updated by Apple.

Symptom

When connecting with Mac OS Server Admin in AppleShare IP 6.3.3, you see an alert box with this message:

> "There were problems loading the module "<module name>" so it was ignored."

Figure 1 AppleShare IP 6.3.3 alert box

Note: This alert box appears for each module, not just the ARA Server Module.

Solution

1. Use the Extensions Manager to disable the SLP Plugin extension on the AppleShare IP 6.3.3 Server.

2. Make sure that there are no duplicate serial numbers on any AppleShare IP Servers connected to the network. See technical document 60602: "**AppleShare IP 6.3: Serial Number Issues**"

TA46136_MacTCP_CDEV_and_EtherTalk_(TIL07513).pdf

MacTCP CDEV and EtherTalk

I have an EtherTalk board in my Macintosh II and am using MacTCP and NCSA Telnet to talk to campus mainframes through an Ethernet backbone.

When I select Ethernet in the MacTCP CDEV, I can connect to a host through Ethernet. However, when I have EtherTalk selected, I cannot make a TCP connection to any host. Shouldn't I be able to make a connection with EtherTalk selected?

This article has been archived and is no longer updated by Apple.

```
EtherTalk in MacTCP is for sending AppleTalk packets with encapsulated TCP.
Use this choice for networks that must go through a DDP/IP router. The
Ethertalk setting creates the Datagram Delivery Packets that the router
expects.

Your network apparently has direct access to the TCP host, which lets you
use the straight packets (Ethernet choice).  The way to look at this
setting is that it's one or the other, not both.
```

WebObjects 5 Deployment: Apple Netname Server Startup Error on Windows 2000

This document describes how to correct the Apple Netname Server startup error during startup after installation of WebObjects 5.0 Deployment on Windows 2000.
This article has been archived and is no longer updated by Apple.

Symptom

After an installation of WebObjects 5.0 Deployment on Windows 2000, the System Event Log shows the following message from the Apple Netname Server: "The Apple Netname Server depends on the following nonexistent service: Apple_Mach_Daemon." Neither of these services are used by the Deployment components and should not have been installed.

Solution

This issue is expected to be corrected in a future version of the product. In the meantime follow these steps to disable the Apple Netname Service:

1. Choose the Start Menu->Settings->Control Panel->Administrative Tools->Services
2. Select the Apple Netname Server and then the menu option Action->Properties
   Note: An alert box with this message may appear: "Configuration Manager: The specified device instance handle does not correspond to a present device." Click OK to continue.
3. Change the Startup type from Automatic to Disabled.
4. Click Apply
5. Click OK.

This disables Apple Netname Services.

Published Date: Feb 18, 2012

WebObjects: WODisplayGroup Delegate Method Does Not Function

The WODisplayGroup delegate method displayGroupDidSetValue described in the WebObjects documentation does not work in a WebObjects application.
This article has been archived and is no longer updated by Apple.

Symptom

Using the WODisplayGroup delegate method displayGroupDidSetValue in a WebObjects application does not work.

Solution

None for WODisplayGroup. However, this delegate method works properly with EODisplayGroup in Enterprise Objects Frameworks (EOF).

Additional Information

Display Group Description

A display group transports values between an enterprise object and a user interface object. An EODisplayGroup is used in a desktop application with Enterprise Objects Frameworks (EOF), while a WODisplayGroup is used in a WebObjects application. The functionality of a WODisplayGroup and an EODisplayGroup are identical.

The WODisplayGroup delegate method described below informs the delegate that `aDisplayGroup` has altered a property value of anObject.

`key` identifies the property, and value is its new value.

Objective-C: (WebObjects Release 4.5 and 4.5.1)

-(void) displayGroup:(WODisplayGroup *) aDisplayGroup didSetValue: (id) value forObject: (id) anObject key: (NSString *) key

Bridged Java: (WebObjects Release 4.5 and 4.5.1)

Package: com.apple.yellow.webobjects

```
public abstract void displayGroupDidSetValue( WODisplayGroup aDisplayGroup, Object value, Object anObject, String key)
```

Pure Java: (WebObjects Release 5 and WebObjects 5.1)

Package: com.webobjects.appserver

public abstract void displayGroupDidSetValue(WODisplayGroup aDisplayGroup, Object value, Object anObject, String key)

However, this method is only implemented for EOF applications. Its counterpart in WebObjects does nothing because this delegate method relies on the implementation of EOAssociation, for which there is no equivalent in WebObjects.

Important: This method has been removed in WebObjects 5.2

Macintosh IIfx: How to Troubleshoot a Monitor/48 Card Problem

We have four Macintosh IIfx systems with the same problem. Each computer is running System 6.0.5 with an Apple 4-bit video card and the Macintosh Display Card 4*8. The cards drive a Macintosh High-Res RGB monitor and a Macintosh Two-Page Display. The color monitors come up, but the Two-Page Displays don't. The same configuration using the old Two-Page Display card and the 4-bit card works fine. What's the problem?

This article has been archived and is no longer updated by Apple.
Here is a troubleshooting sequence that may help you locate the culprit:

1) Start up with a known-good System disk with no INITs installed. Some INITs cause problems with video.

2) Try swapping out the 4*8 card if you haven't already done so.

3) Using the original configuration, insert the 4*8 (the card driving the Two-Page) into a different slot. There might be a problem with the bus lines or the slot itself.

4) Swap the logic board, if the slot or bus is the problem.

Spooler Problem with PostScript Interpreter

Article Reviewed Only: 9 June 1992

When I print a multi-page document - say, 3 pages - all pages spool to the spooler as shown in the print spooler window of AppleShare 2.x. The printer initializes and prints page 1 without problem. Either of two things can happen with page 2:

* It never prints or even gets started by the spooler. Thus, the pages to print are 3 and printed pages are 1.

* The job is flushed with an error sheet stating any of the following:

undefined;OffendingCommand: ^^^^^^^^ (these are upside down on sheet),
undefined;OffendingCommand:CE6F43C216B8D
,dictfull;OffendingCommand:def,limitcheck;offending command:^^^^^^^A3
(strange foreign characters), canceled by user.

If I send only one page at a time to the spooler, everything works well, but it's not very efficient.

This article has been archived and is no longer updated by Apple.
The error messages you received are not related to memory, but to the PostScript Interpreter which resides in the printer.

In general, there appears to be an issue with how the AppleShare print server (version 2.01) is handling PostScript files. The amount of required memory on the print server when capturing one printer is 2MB. The additional memory is not used. The problem would more likely center on how the files are being handled on by the Print Server/LaserWriter. The problem is being reported from the printer.

The "OffendingCommand" is telling us that the interpreter does not understand what has been requested--that is, a Syntax Error is being reported. The "dictFull" error is a report from the PostScript dictionary resident in the printer.

The probability is that packets are getting damaged somewhere in the spooling process on the print server. When the PostScript interpreter receives these damaged packets, it returns the error message or flushes the print job. This could point to a variety of problems with the installation of the server's software.

One thing that may cause this problem involves whether your system has ever run an earlier version of the operating system (and Print Server) before System 6.0.5. If so, you may want to try trashing the ServerFolder and reinstalling the system software and print server. Important: If you do this, make sure you use the Network Products Installer disk to install the print server. The Installer that ships with print server may not work correctly with either 6.0.4 or 6.0.5, but the Network Products Installer will. You may find that you need to reformat and reload the entire hard drive to resolve this problem. Also consider moving up to System 7 and installing AppleShare 3.0.

Mac OS X: How to Export a Directory to a Subnet

This document explains how to export a directory to a specific subnet using NFS. This technique restricts access to an NFS export to computers that are in a specified subnet. It can also be used to export more than one directory when exporting to clients or netgroups is not a viable option. This article has been archived and is no longer updated by Apple.

How to Export a Directory to a Subnet

1. Create a new directory inside "/" directory using NetInfoManger and name it "exports". All of the exported directories are configured from within the new directory.

2. Create a new directory for the directory you want exported inside `/exports`.

   In this document, `/Applications` is used as an example.

   □

   Figure 1 Initial `/Applications` directory

3. Create a new property in `/Applications`.

   A. Click Name Property

   B. Choose New Property from the Directory menu.

   This creates a new property called `new_property` with a value of `new_value`.

   C. Change `new_property` to `opts`

   Additional values need to be created for the opts property (done in step 4)

   D. Change `new_value` to `mapall=nobody`

4. Select opts

5. Choose New Value from the Directory menu.

6. Change the value to `network=xxx.xxx.xx.x`

   `xxx.xxx.xx.x` is your network IP address (example, 192.168.42.0)

   Important: The network value must contain a 0 in the last octet. This specifies the entire subnet.

7. Choose New Value from the Directory menu.

8. Change the value to `mask=xxx.xxx.xxx.x`

   `xxx.xxx.xxx.x` is the subnet mask (example, 255.255.255.0)

If a directory needs to be exported to more than one subnet, use `network=192.0.0.0` and `mask=255.0.0.0`. This exports the directory to the entire 192 network.

The final `/Applications` directory should look similar to figure 2.

□

Figure 2 Final `/Applications` directory

Important: You must restart the computer for any changes that are made to the exports directory in NetInfoManager to take effect.

How to Export the Same Directory to Multiple Subnets

1. Create an export for the first subnet following the steps described in How to Export a Directory to a Subnet.
2. Duplicate this directory.
3. Remove the word copy from the name of the duplicated directory.
4. Change the network= value to the new subnet value.

Repeat steps 1 through 4 as necessary to cover all subnets.

5. Restart the computer.

iMovie 2.1.1 for Mac OS X: iMovie Help Pictures Appear in English only

iMovie Help is available in all languages, however the pictures appear only in English regardless of which language iMovie Help is viewed in.
This article has been archived and is no longer updated by Apple.

Symptom

In iMovie Help the text appears in the language of the operating system, however pictures and screenshots appear only in English.

Solution

Unfortunately, due to data storage limitations on the install CD, there was not enough room to include pictures in all languages. None of the graphics containing text with alternate languages are currently available. However, this does not affect the functionality of Mac OS help.

Kensington Turbo Mouse: Using with System 6.0.5 Requires Patch

My Macintosh IIx (running System 6.0.5.) freezes when the system is starting up. The problem is intermittent and happens only when the mouse--a Turbo Mouse from Kensington--is plugged in. (We have swapped out the mouse and the keyboard.)

This article has been archived and is no longer updated by Apple.
The Turbo mouse has a problem with System 6.0.5. Kensington has a patch for this. For contact information, search the Tech Info Library under "Kensington".

WebObjects 5: Saving an Enterprise Object with NSArray or NSMutableArray as a Custom Value Class Causes Exception

This document provides an example to workaround an issue in WebObjects 5 where saving an Enterprise Object (EO) Class that has either a NSArray or a NSMutableArray as a custom value class for the attribute in an entity creates an exception.
This article has been archived and is no longer updated by Apple.

Symptom

Using an NSArray or an NSMutableArray as a custom value class for an EOAttribute in an EOEntity with the conversion method "archiveData" causes the following exception when saving:

> "Error encountered converting value of class com.webobjects.foundation.NSMutableArray to type specified in attribute 'myAttribute' of entity 'MyEntity'."

and the conversion exception is :

> Class com.webobjects.foundation.NSMutableArray does not implement method archiveData

Solution

In WebObjects 4.0 - 4.5 there is an Objective-C category to NSObject that implemented the method "archiveData". This category is not available in WebObjects 5. To get the same function, you must create a subclass of NSMutableArray and add the conversion methods and user's implemention to that class. The example below shows how a custom class called CustomMutableArray is created which extends NSMutableArray and implements the archiving method "archiveData".

```
//
// CustomMutableArray.java
//

package com.mycompany.utilities;

import java.io.*;
import java.util.*;
import com.webobjects.foundation.*;

/**
* This class demonstrates how to create a custom value class.
* This particular class is a subclass of NSMutableArray which can be used
* within EOModeler.
*/

public class CustomMutableArray extends NSMutableArray {
    /** This helps create the ByteArrayOutputStream with a good space estimate. */
    private static final int kOverheadAdjustment = 512;

    /** This also helps create the ByteArrayOutputStream with a good space estimate. */
    private static final int kCountBytesFactor = 16;

    /** This determines, when an error occurs, if we should throw an NSForwardException or just return null.
*/
    private static final boolean kThrowOnError = true;

    /**
    * This is the factory method.  Rename as appropriate from your EOModel.
    * It uses java Serialization to turn bytes from an NSData into a reconstituted Object.
    *
    * @param data This is the NSData holding the previously serialized bytes.
    * @return The un-serialized Object.
    */

    public static Object objectWithArchiveData(NSData data) {
```

```
ByteArrayInputStream bis = new ByteArrayInputStream(data.bytes());
Object result = null;
Throwable exception = null;
try {
   ObjectInputStream ois = new ObjectInputStream(bis);
   result = ois.readObject();
} catch (IOException ioe) {
   exception = ioe;
} catch (ClassNotFoundException cnfe) {
   exception = cnfe;
}

if (exception != null) {
   if
(NSLog.debugLoggingAllowedForLevelAndGroups(NSLog.DebugLevelCritical,
NSLog.DebugGroupArchiving)) {
NSLog.debug.appendln(exception);
   }

   if (kThrowOnError) {
throw new NSForwardException(exception);
   }
}

return result;
    }

    /**
    * This is the conversion method.  Rename as appropriate from your EOModel.
    * It uses java Serialization to serialize this object into bytes within an NSData.
    *
    * @return An NSData object containing the serialized bytes of this object.
    */

    public NSData archiveData() {
ByteArrayOutputStream bos = new
ByteArrayOutputStream(kOverheadAdjustment + count() * kCountBytesFactor);
NSData result = null;
try {
   ObjectOutputStream oos = new ObjectOutputStream(bos);
   oos.writeObject(this);
   oos.flush();
   oos.close();
   result = new NSData(bos.toByteArray());
} catch (IOException ioe) {
   if
(NSLog.debugLoggingAllowedForLevelAndGroups(NSLog.DebugLevelCritical,
NSLog.DebugGroupArchiving)) {
NSLog.debug.appendln(ioe);
   }

   if (kThrowOnError) {
throw new NSForwardException(ioe);
   }
}

return result;
    }
}
```

Final Cut Pro: German Manual Contains Contradictory Field Dominance Information

This document explains the proper use of field dominance. There is contradictory information in the German Final Cut Pro 2.0 manual.
This article has been archived and is no longer updated by Apple.

Symptom

The German Final Cut Pro 2.0 manual provides contradictory information about the field dominance to use for DV captured using FireWire on pages 128, 331 and 456.

Solution

- Digital Video (DV) captured using FireWire, should always have the field dominance to set to lower (even).
  Lower (even) is translated to German "gerade Zeilen".

  In the German manual pages 331 and 456 suggested to set the field dominance to upper (odd) which is "ungerade Zeilen" in German. The correct information is provided on page 128.
- The translation error is expected to be corrected in the next edition of the manual.

WebObjects 5.0: Key-Value Coding Access Throws NSKeyValueCoding$UnknownKeyException

Java package access variables cannot be accessed using key-value coding (`NSKeyValueCoding`) unless Java code changes are made.
This article has been archived and is no longer updated by Apple.

Symptom

When WebObjects tries to get or set a Java package access variable with no accessor methods using key-value coding, a `NSKeyValueCoding$UnknownKeyException` is thrown. This can occur after the conversion to Java of an Objective-C class that does not implement accessor methods for all instance variables.

Solution

To access Java package access variables using key-value coding, one of the following must be done in order of preference:

- Accessor methods must be implemented.
- Package access variables must be made public.
- `KeyValueCodingProtectedAccessor` must be implemented in the package.

Implementing `KeyValueCodingProtectedAccessor` is the least preferred solution because it imposes a significant performance penalty, so this should be considered a temporary solution until one of the more preferred solutions has been implemented.

For additional details, see the NSKeyValueCoding.ValueAccessor class description at Apple's Developer Web site.

WebObjects 5 (Windows): How to Change the Web Server after Installation

When using WebObjects 5.0, 5.1, or 5.2 on Microsoft Windows, WebObjects needs to know when the web server changes. This document explains how to change the web server after you install WebObjects.
This article has been archived and is no longer updated by Apple.
WebObjects maintains the information about the web server in two configuration files which must be updated when the web server changes.

Changing the Configuration Files

Note: The examples provided assume WebObjects is installed in C:\\APPLE

1. Stop the web server application.

2. The following steps suppose that you stopped your web server application.

3. Copy the contents of the old web server's scripts directory to the new web server's scripts directory. The script directory is normally named
"Scripts" in inetpub or "cgi-bin".

4. Copy the contents of the old web server's document root directory to the new web server's document root directory.

5. Modify `WebServerConfig.plist` in `C:\\APPLE\\Library\\Frameworks\\JavaWebObjects.framework\\Resources\\`. Change the line that sets the DocumentRoot property. This should be set to the full path of the document root.

6. In the same file, change the property `WOAdaptorURL`. It should be set to the path of the scripts directory relative to the web server root. For example, if the scripts directory is `C:\\www\\cgi-bin\\` and the root of the webserver is `C:\\www\\`, the `WOAdaptorURL` property should be set to `cgi-bin`.

7. Modify WebServerConfig.plist in `C:\\APPLE\\Library\\Configuration`. Make the same changes to the `DocumentRoot` and to the `WOAdaptorURL` properties.

Verifying the Installation

You can check the installation by accessing the WebObjects Adaptor Information Page after restarting the web server. The WebObjects Adaptor Information Page must be enabled first. The following link has the steps to enable the page:

"Setting Access to the WebObjects Adaptor Information Page"

Once the page is enabled, then you can access the WebObjects Adaptor Information Page several ways, two of which are given below.

Method using IIS

http://localhost/scripts/WebObjects.dll/WOAdaptorInfo?username+password

Method using a CGI

http://localhost/cgi-bin/WebObjects.exe/WOAdaptorInfo?username+password

Information about the latest update of WebObjects for Windows is always available in the document titled "WebObjects Current Patch List".

Mac OS 9: Desktop Printer Menu Extension Disabled by Multiple Users

In any version of Mac OS 9, if the Multi-User Startup system extension is installed, the Desktop Printer Menu extension is not active.
This article has been archived and is no longer updated by Apple.

Symptom

The Desktop Printer Menu extension is installed, but there is no Desktop Printer menu in the menu bar.

Solution

An implementation of the Desktop Printer menu is provided by the Limited and Panels environments. As a result, the Desktop Printer menu extension is not displayed in the Finder environment.

If you are not using the Multiple Users feature, use the Extensions Manager control panel to turn off the Multi-User Startup extension and the Desktop Printer menu will become available in the Finder.

ImageWriter Family & Scribe: Connecting To An IBM PC, PS/2, AT&T

What are the cable and printer configurations that will interface an IBM PC, PS/2, AT&T 6300 or other IBM compatible to an ImageWriter I, ImageWriter 15", ImageWriter II, LQ or Scribe printer.
This article has been archived and is no longer updated by Apple.

Cabling pinouts for a custom cable:

IBM PC (use female DB-25)	ImageWriter II or ImageWriter LQ (use circular 8 connector)
5,6 (CTS, DSR)	1 (DTR)
20 (DTR)	2 (DSR)
3 (RxD-)	3 (TxD-)
7 (SG)	4,8 (SG, RxD+)
2 (TxD-)	5 (RxD-)

IBM PC (use female DB-25)	ImageWriter/15"/Scribe (use male DB-25)
3 (RxD-)	2 (TxD-)
2 (TxD-)	3 (RxD-)
5 (CTS)	4 (RTS)
7 (SG)	7 (SG)
6 (DSR)	20 (DTR)

Reference: RS232 Signal (DB-25 DTE)

1	Sig Gnd	Normally Shield or Chassis Ground
2	TXD	Transmit Data
3	RXD	Receive Data
4	RTS	Request to Send
5	CTS	Clear to Send
6	DSR	Data Set
7	GND	SIGNAL Ground
8	DCD	Data Carrier Detect
20	DTR	Data Terminal Ready
22	RI	Ring Indicate

Set printer switches to the following settings for this configuration:

- U.S. Character set
- 66 lines per page
- 8 data bits (1 stop bit, no parity)
- pica character pitch
- no LF after CR
- 9600 Baud
- Data Terminal Ready Protocol

ImageWriter I Switch Settings:

Switch 1

Position	1	2	3	4	5	6	7	8
Closed (On)	-	-	-	-	-	-	-	-
Open (Off)	X	x	x	x	X	x	x	x

Switch 2

Position	1	2	3	4

Closed (On)	x	x	-	
Open (Off)	-	-	X	

ImageWriter II Switch Settings:

Switch 1

Position	1	2	3	4	5	6	7	8
Closed (On)	-	-	-	-	-	-	-	-
Open (Off)	X	x	x	x	X	x	x	x

Switch 2

Position	1	2	3	4	5*	6*
Closed (On)	X	x	-	-		
Open (Off)	-	-	X	X		

*** NOTE:** DO NOT CHANGE SWITCH 5 AND 6.

ImageWriter LQ Switch Settings:

Switch1

Position	1	2	3	4	5	6	7	8
Closed (On)	-	-	-	-	-	-	-	-
Open (Off)	X	x	x	x	X	x	x	x

Switch2

Position	1	2	3	4	5	6	7	8
Closed (On)	X	x	-	-	-	-	-	-
Open (Off)	-	-	X	X	X	x	X	x

Switch 3: DO NOT TOUCH!

Finally, configure the serial port of the computer to match the printer configurations as above and assign the port to LPT1 by running this autoexec program:

mode COM1:96,N,8,1,P
mode LPT1:=com1

Software Drivers

These Apple printers were designed for use with Apple II and Macintosh computers, and contain many useful design features accessible only by those systems. Some of the printers have some similarity in design with printers that were designed, tested, and sold for PC users. Therefore, there is a remote possibility that PC drivers may control some of the functions on these printers. We have no knowledge which drivers may or may not work. If you wish to pursue this, some starting points:

Printer	PC Driver
ImageWriter II	Epson FX or similar driver
StyleWriter	Canon BJ-20
StyleWriter II	Canon BJ-200 (possibly also the BJ-200e)
Color StyleWriter (early models)	Canon Color BJ-600

Macintosh Compact Models: "Hourglass" Effect on Screen

My Macintosh SE/30 screen displays severe "hourglassing" when there is a large, black area on the screen. I drew a black rectangle (wider than it is high) in MacDraw and then moved it around the screen. The left and right sides of the screen closest to the rectangle squeeze in towards the rectangle (hourglassing). I have replaced everything in the unit at least once. I also removed the hard disk, but that had no effect.

This article has been archived and is no longer updated by Apple.

The hourglass effect is common to all of the compact Macintosh computers. It's more pronounced on some systems than on others. To reduce (but not eliminate) the effect, turn down the internal brightness level. Try this and experiment with other compact Macintosh computers.

iTunes 2 for Mac OS X: What to Do If You Experienced Data Loss During Installation

Users who have experienced data loss during iTunes 2 for Mac OS X installation have reported successful restoration of files using file recovery applications.
This article has been archived and is no longer updated by Apple.
Users who have experienced data loss during iTunes 2 for Mac OS X installation have reported successful restoration of files using file recovery applications.

If you have experienced data loss during iTunes 2.0 for Mac OS X installation, it is important that you do not perform any operations that would write data on the affected partition.

Here are two products that offer the ability to recover lost data:

- Norton Utilities for the Macintosh by Symantec Corp.
- TechTool Pro by MicroMat Computer Systems.

Both offer diagnostic software including hard drive diagnostics, data recovery, and other utilities. When using either of these products to attempt to recover your data, use the feature to recover erased files and not the feature to repair or recover volumes.

Most of these products recommend you restart your computer from a CD before attempting to recover data.

If you are a U.S. customer and require further assistance, or have additional questions, please contact AppleCare at (800) 275-2273. If you are located outside the United States, please refer to the Service and Support Guide that came with your computer or visit http://www.apple.com/support/ and choose your country from the multi-lingual support pop-up menu at the bottom of the page.

Information about products not manufactured by Apple is provided for information purposes only, and does not constitute Apple's recommendation or endorsement. Please contact the vendor for additional information.

The following document can help you search for a particular vendor's address and phone number:

WebObjects 5.0: WebObjects 5.0 Application May Not Update Frames Correctly

This document describes how to make sure content within frames is updated.
This article has been archived and is no longer updated by Apple.

Symptom

Frames are not updated in WebObjects 5.0 when they should be updated.

Solution

Use `setPageRefreshOnBackEnabled(false)` in your WebObjects application. In WebObjects 5.0 this keeps pages from being cached and frames will work as expected.

Additional information

WebObjects 4.5 and earlier would update frames each time an event occurred such as clicking a submission button. However, in WebObjects 5.0 the caching method is changed. This results in frames not being updated since the contextID is found and assumes that the page was reloaded or backtracked. In the case of frames, a cached page is displayed rather than generating a new page.

HyperCard 1.2.5: Multi-launching From a Server

Our school's Macintosh lab has an AppleShare server. I want to set up a single copy of HyperCard (1.2.5) with several stacks on the server, so that it can be multi-launched. The HyperCard stacks and applications on the server are locked (Finder), and they do not have any problems. Is there a way to do it?

This article has been archived and is no longer updated by Apple.

HyperCard can multi-launch on the server. It works if HyperCard is either locked or in a locked folder. We experimented and got an error message by unlocking HyperCard or by putting it in a write-enabled folder. Stacks work the same way.

Apple IIc: Use Mouse Designed for Macintosh

I have a question concerning the "platinum" Apple IIc and a mouse. When I'm using the mouse, the cursor starts at the top-left corner and moves straight down to the bottom-left corner of the screen. Why?

This article has been archived and is no longer updated by Apple.

You have come across an incompatibility in mouse timing. The mouse sold for the Apple IIc works properly, and mice received from service work properly. However, mice that came from Macintosh Plus systems sometimes work and sometimes not, depending on the manufacturer.

To assure proper operation, make sure you use a mouse that was designed for use with the IIc.

Apple IIe: Difficulty Starting Up when Connected to a TV Monitor

My Apple IIe won't power up its disk drive when connected to a TV monitor.

This article has been archived and is no longer updated by Apple.
If your RF modulator is the type that gets its power from the Apple IIe, the power supply could be the problem. Try unplugging one or more interface cards and see if the computer can power up with the RF modulator. If this works, try a new power supply. If it still refuses to power up, suspect a bad RF modulator.

Apple IIGS: How to Mix a 3.5-inch Drive with Other Drives

I am using an Apple IIGS with a DuoDisk drive and a single 5.25-inch drive. The controller cards are in slots 5 and 6. I want to use a 3.5-inch drive along with the other drives. I installed an Apple UniDisk 3.5-inch drive with its controller in slot 4 and tried slot 7 with no success. I changed the slot settings under the Control Panel each time. How can a 3.5-inch drive be used with the described 5.25-inch drives?

This article has been archived and is no longer updated by Apple.
Try this configuration:

1) Plug the UniDisk 3.5-inch directly into the back of the computer (no controller).

2) Plug the DuoDisk into the port on the UniDisk 3.5 disk (no controller).

3) Plug the single 5.25-inch UniDisk into a controller card in slot 7.

Set the Control Panel as follows:

slot 5 smart port
slot 6 disk port
slot 7 your card
startup scan

This configuration tries first to start up from the UniDisk 5.25. If no disk is found, then it looks to drive 1 of the DuoDisk. If no disk is found, then it goes to the UniDisk 3.5.

AppleScript: Scripts Do Not Recognize Disks with Accent Characters in Name

This document describes an issue where disks or files with accented characters are not recognized.
This article has been archived and is no longer updated by Apple.

Symptom

If a disk or file contains an accented character, such as é, ü, ê, or à, or a character from a double-byte language (for example, Japanese) its name string cannot be coerced into an alias.

Products Affected

- AppleScript

Solution

- Rename the file or disk removing the accented characters.
- Leave the name as is and use Choose File or Choose Folder to let the user locate the correct item.

WebObjects 5.1: Cannot Connect to Annotated Version of PetStore Example

This document describes an issue when running the PetStore EJB example using WebObjects 5.1.
This article has been archived and is no longer updated by Apple.

Symptom

Following the steps in the PetStoreEJB README results in a working PetStore, however the link to the annotated version of the PetStore does not work. Clicking the link results in the message: "The requested resource (/estore/annotation/ann_overview_j2ee.jsp) is not available."

Solution

The servlet context specified in the README is incorrect. The context must have a path of "/estore", not "/petstore". The "/estore" path is hard-coded into the example, so it must be used. Make the following changes to the README:

1. For step 4 ("Prepare Tomcat"), the beginning of the server.xml file should read:

```
<!-- Java Pet store context -->
<Context path="/estore" docBase="petstore" debug="0" reloadable="true">
```

2. For step 9 ("Connect to Java Pet Store Demo"), the URL should be:

http://localhost:8080/estore

Apple IIGS: When One Hard Drive Shows Two Icons

I have an Apple IIGS with 1.25MB RAM, a 3.5-inch floppy drive, 5.25-inch floppy drive, and an HD 20SC hard disk.

I removed all data from the HD 20SC to install System 5.0. Now, I see multiple hard-drive icons. What happened? Should I re-format the disk?

This article has been archived and is no longer updated by Apple.
Most likely, you accidentally created more that one partition. (This may also have happened if the drive was previously used on another operating system, such as the Macintosh OS.)

You need to go back to Advance Disk Utilities and select Partition. Remove all partitions, then create a new one.

WebObjects 4.5.1: Interface Builder Unexpectedly Quits When Using Mac OS X

If you install WebObjects 4.5.1 on Mac OS X, InterfaceBuilder may unexpectedly quit after you form a connection between objects.
This article has been archived and is no longer updated by Apple.

Symptom

Shortly after you form a connection, Interface Builder unexpectedly quits.

Solution

For developers not building EOF applications

If you do not plan to use Interface Builder to create EOF applications, the best workaround is to remove or disable the EOF palette. To disable it, follow these steps:

1. Quit Interface Builder if it is open.
2. Open a Terminal window, then copy and paste in these lines:

```
cd /Developer/Palettes
mv EOPalette.palette EOPalette.palette.disabled
```

3. Open Interface Builder.
4. Dismiss the alert with this message "Unable to load palette..."
5. From the menu, choose **`Tools > Palettes > Palette Preferences...`**
6. Select "EOPalette" from the list.
7. Click Remove .
8. Close the Preferences window.

If you later want to use the palette, you can follow these steps to re-enable it:

1. Quit Interface Builder if it is open.
2. Open a Terminal window, then copy and paste in these lines:

```
cd /Developer/Palettes
mv EOPalette.palette.disabled EOPalette.palette
```

3. Open Interface Builder.
4. From the menu, choose **`Tools > Palettes > Palette Preferences...`**
5. Click Add.
6. Navigate to **`/Developer/Palettes`**, choose EOPalette.palette, and click Open.
7. Close the Preferences window.

For developers building EOF applications

If you plan to use Interface Builder to create EOF applications, there is no simple workaround.

One approach is to avoid using the EOPalette functionality in Interface Builder and instead programmatically create connections, typically in your implementation of **`awakeFromNib`**.

Another approach is to do non-EOF work in Interface Builder by temporarily disabling EOPalette using the above steps, then re-enable it to

perform EOF-specific tasks. During the time the palette is enabled, Interface Builder may quit each time you create a connection (or do anything which shows the Connections inspector). If you save your work immediately after making each connection, quit and reopen Interface Builder, you can use EOPalette, although you must reopen Interface Builder quite often.

LaserWriter: Blank Test Page May Be From Downloaded PostScript

My LaserWriter IINTX works normally, except that the test print page is blank. The unit prints all other pages with no problem. What does this mean?

This article has been archived and is no longer updated by Apple.
If you have downloaded any PostScript programs to the printer, the test page may have been blanked out unintentionally. If this is the case, the fact that the sheet is blank does not point to any hardware failure.

If you have not downloaded any PostScript programs the blank test page could be a sign of future I/O problems.

ProDOS: How to Convert DOS 3.3 Files

I want to convert DOS ASCII and other formats into ProDOS format. Is there a disk that will convert DOS 3.3 to ProDOS?

This article has been archived and is no longer updated by Apple.

The current version of System Utilities 3.1 handles the conversion from DOS 3.3 to ProDOS automatically during a copy. This disk was included with the Apple IIe and IIc Plus.

WebObjects 5: How to Configure an Oracle Stored Procedure With EOModeler

This document explains how to configure an Oracle stored procedure with EOModeler and highlights the differences going from WebObjects 4.5 to WebObjects 5.
This article has been archived and is no longer updated by Apple.

Applicable products

- WebObjects 5.1
- WebObjects 5.2

The Oracle Adaptor in WebObjects 4.5 passed stored procedure arguments by name. However, WebObjects 5 uses the JDBC API, which passes stored procedure arguments by order. The JDBC Adaptor uses the alphabetical order of the "columnName" of the arguments in the EOStoredProcedure to define the order of the arguments for the stored procedure call.

The "column" name is relevant here, not the name shown in the "Name" field of EOModeler. Use the EOModeler inspector to look at the "column" name of each parameter, or use the "Add Column" command at the bottom of EOModeler to add the "column" to the display.

The EOModeler tool can be used to reverse engineer your stored procedures. By default, EOModeler uses strings of numbers like 001 and 002 for the column names to emphasize the order. If you have an existing model file, you can use the EOModeler "New Updated Model" command to regenerate the model file.

Example 1: The stored procedure has only IN and OUT parameters.

The stored procedure expects three arguments in the following order: username(IN), password (IN), and authId (OUT).

After reverse-engineering, EOModeler automatically assigns a column name like "001" for username, "002" for password, and "003" for authId to show the order of execution for the arguments.

EOModeler displays the following:

Example 2: Your stored procedure expects a result set.

An Oracle stored procedure does not produce a result set in the usual way. Instead, it uses an Oracle-specific REF CURSOR parameter to provide access to results. The JDBC adaptor offers limited support for the Oracle REF CURSOR only as the return value for an Oracle stored function, not as an OUT parameter for an Oracle stored procedure.

To work around this issue, rewrite the Oracle stored procedure as a stored function. In Oracle, the function is created with the SQL command "CREATE FUNCTION" instead of "CREATE PROCEDURE", which is used for procedures.

In EOModeler, the Oracle stored function is modeled in the same way as any stored procedure. The external type of the returnValue parameter should be set to "REF CURSOR", even though this is not in the pop-up list of supported types -- you need to type in "REF CURSOR". Its column name should be "000" (a string of three zeroes) to indicate that it is a return value from the stored function.

Known Issues

1. EOModeler cannot reverse stored functions or stored procedures defined inside a package.

Workaround: Do not use packages. Or if you have to use packages, first define the stored procedure in your model file manually (not-reverse-engineered) using the EOModeler tool. Then, be careful to use the correct name for the stored procedure. For example, if the package name is "P" and the stored procedure name is "proc" in the database, then the external name of the stored procedure in your model file should be named "P.proc". To verify that the external name is properly:

1. Ensure EOModeler tool is set to the 'Table' mode.
2. Select 'Stored Procedures' to view all stored procedures with their internal and external names.

2. When reverse-engineering a stored function with a REF CURSOR, EOModeler sometimes adds an extra parameter with the external type PL/SQL RECORD, which causes an exception at run-time (Java.lang.NullPointerException).

Workaround:

1. Manually remove all extra OUT parameters, in particular the one of type PL/SQL RECORD.

2. Use the EOModeler Inspector to view the column named 'returnValue'.

3. Using the Inspector, add a false factory method, for example, name it 'factoryMethod') and a false conversion method (for example, name it 'convMethod'. Select 'Bytes' as the value for 'Init Arguments' using the pop-up menu.

4. Save the model file.

Example of a stored function reverse-engineered by EOModeler before any modifications:

Example of the same stored function after modifications:

EOModeler's Inspector showing the column 'returnValue' after modifications:

Macintosh: When DAs Can‘t Be Accessed

I have a Macintosh II using System 6 that cannot run desk accessories or even access the control panels with MultiFinder running. The machine beeps once if you try to select General or other items.

This article has been archived and is no longer updated by Apple.
Under System 6, this condition is usually caused by the omission of the DA Handler file from the System Folder. Sometimes the file is there, but it is corrupted. Try replacing it by reinstalling System software.

If this situation happens while under System 7, try restarting the Mac and hold down the Shift key as it starts back up. This will keep any extensions from loading that may be conflicting with the actions you are taking. If this doesn't work, consider reinstalling the system software.

Published Date: Feb 18, 2012

Macintosh System Errors: Possible Sources

I just installed a new hard disk in my Macintosh II and am getting all sorts of system errors. The dealer who installed the hard drive insists that the problems are not hardware-based. The only software that I have been able to install is System 6.0.5.

Trying to install anything else generates system errors. (Sometimes just starting the computer and opening the System Folder generates errors.) I get errors ID =10, ID =28, ID =03, and ID =01, not to mention a "line 1111 trap error."

This article has been archived and is no longer updated by Apple.
Most system errors sound like gibberish to most of us, but if you were writing a new program for the Macintosh, the error number would tell you that you have a problem with your code. But, when you are running a compiled program and get this error, all it tells you is that the software crashed. Some errors, like 25, are "out of memory." This one does make sense. In your case, check through these possible problems:

1) This is a third-party drive that was formatted with HD Setup. You have to use a utility from the third-party manufacturer to format a third-party drive. Apple's utility is only for Apple's hard drives.

2) The hard drive is defective.

3) Some other file within the System Folder is causing the crashes: a screen dimmer, startup sound, electronic mail, or something similar.

4) The computer could have a memory problem in RAM or the logic board.

iMovie: iMovie Unexpectedly Quits When Accessing iMovie Help

Third-party iMovie plug-ins may prevent iMovie Help from opening.
This article has been archived and is no longer updated by Apple.

Symptom

iMovie unexpectedly quits when attempting to open iMovie Help.

Products affected

- iMovie 2.x
- Roxio Toast prior to version 5.1.3

Solution

Roxio Toast installs a VideoCD plug-in which can be used with iMovie. Versions of the VideoCD plug-in prior to version 1.5 may cause iMovie to unexpectedly quit when accessing iMovie help.

- Update to Roxio Toast version 5.1.3 or greater.
  Toast v5.1.3 installs VideoCD v 1.5, which resolves this issue. Updates for Toast are available from Roxio's website
- Disable the VideoCD plug-in.
  You can also disable the Roxio VideoCD.

Disabling the VideoCD plug-in

1. Open /Library/Quicktime
2. Remove ToastVideoCDExport.component

MacDFT, PF10 Function, and 32798 Error

I am running MacDFT on my Macintosh IIcx, with System 6.0.5. I am accessing PROFS from our mainframe. When I ran version 1.0 of MacDFT I was okay, but as soon as I upgraded to version 1.1, I began experiencing problems when I used the PF10 function. The system hangs and reports a 32798 error and that communication with the host has been lost. I did try switching settings within the program, but to no avail. We are using a coax connection.

This article has been archived and is no longer updated by Apple.
A 32798 error is a TIMEOUT_ERR, or "request timed out" and suggests a problem between the terminal and controller. We have seen similar problems when a non-IBM controller is used (Apple only supports IBM 3x74 controllers). And this type of error is much more prevalent when one is using DFT mode as compared to CUT.

MacDFT 1.0 only supported CUT mode, and MacDFT 1.1 supports either. You may be able to use MacDFT 1.1 in CUT mode to work around this problem. However, you may encounter other incompatibilities if you are not using IBM controllers.

A PF10 from the PROFs main menu is an add-on automatic reminder. This worked flawlessly for us during our testing with MacDFT 1.1.

Another possible problem area is the type of cable used. When coaxial devices are designed, we usually assume RG62/AU, but often unshielded and less-expensive cable is substituted, like RG59 or RG58. Either of these latter two cable types could cause problems.

WebObjects 5.1: How to Find the Version of WebObjects and Other Software Installed in Mac OS X

This article provides sample Java code to extract the version of each software package installed on the Mac OS X computer without having to look for the version number of each package in the directory `/Library/Receipts`.

Note: From Mac OS 10.2 onward, this sample code onlys extract the version of WebObjects packages installed in the directory `/Library/Receipts`, not for other software packages.

This article has been archived and is no longer updated by Apple.
The sample function can be defined in any class suitable to your program.

The use of this software is subject to the conditions set out in the license.txt file:

THE SOFTWARE PATCH PROVIDED FROM APPLE IS PROVIDED "AS IS" AND WITHOUT WARRANTY, EXPRESS OR IMPLIED. APPLE SPECIFICALLY DISCLAIMS ANY IMPLIED WARRANTIES OF MERCHANTABILITY AND FITNESS FOR A PARTICULAR PURPOSE. IN NO EVENT WILL APPLE BE LIABLE FOR ANY DAMAGES, INCLUDING BUT NOT LIMITED TO ANY LOST PROFITS, LOST SAVINGS OR ANY INCIDENTAL OR CONSEQUENTIAL DAMAGES, WHETHER RESULTING FROM IMPAIRED OR LOST DATA, SOFTWARE OR COMPUTER FAILURE OR ANY OTHER CAUSE, EVEN IF APPLE IS ADVISED OF THE POSSIBILITY OF SUCH DAMAGES, OR FOR ANY OTHER CLAIM BY CUSTOMER OR FOR ANY THIRD PARTY CLAIM.

Sample Code

In this example, the method

```
public static NSDictionary productVersions()
```

is defined in the file Application.java in a WebObjects application project.

```
import java.io.*;
import com.webobjects.foundation.*;
import com.webobjects.appserver.*;
import com.webobjects.eocontrol.*;

public class Application extends WOApplication {

      private static NSDictionary _productVersions = null;

    public static void main(String argv[]) {
        WOApplication.main(argv, Application.class);
    }

    public Application() {
        super();
        System.out.println("Welcome to " + this.name() + "!");

        /* ** Put your application initialization code here ** */

         System.out.println("Version information:\\n" +
            formattedDictionary(productVersions()));
    }

    public static NSDictionary productVersions() {
        if ( _productVersions != null) return _productVersions;

        // Go to the /Library/Receipts directory to get the software version
        String receiptsDirString = "/Library/Receipts";
        File receiptsDir = new java.io.File(receiptsDirString);

        if (!receiptsDir.exists() || !receiptsDir.canRead())
            return NSDictionary.EmptyDictionary;

        // Extract the version information from each package Contents,
        // Resources folders and software_version file
        try {
            String packageFiles[] = receiptsDir.list();
            int length = packageFiles.length;
            NSMutableDictionary packages = new NSMutableDictionary(length);

            for (int i = 0; i < length; i++) {
                String packageName = packageFiles[i];
                String packagePath = receiptsDirString + "/" + packageName +
```

```
                    "/Contents/Resources/software_version";
                File versionFile = new File(packagePath);

                if (versionFile.exists()) {
                    StringBuffer versionString = new StringBuffer();
                    try {
                        LineNumberReader reader = new LineNumberReader(
                            new InputStreamReader(
                            new FileInputStream(versionFile)));
                        String line = reader.readLine();

                        while (line != null) {
                            versionString.append(" " + line);
                            line = reader.readLine();
                        }
                    }
                    catch (IOException e) {
                        // Flag the exception and return an empty string
                        System.out.println("Raised IOException");
                        return NSDictionary.EmptyDictionary;
                    }
                    if (versionString.length() > 1) {
                        String packageVersion = versionString.substring(1);
                        NSArray packagesForVersion =
                            (NSArray)packages.objectForKey(packageVersion);

                        if (packagesForVersion == null) {
                            packages.setObjectForKey(new NSArray(packageName),
                                packageVersion);
                        }
                        else {
                            NSMutableArray packageVersHolder =
                                new NSMutableArray(packagesForVersion);
                            packageVersHolder.addObject(packageName);
                            packages.setObjectForKey(packageVersHolder,
                                packageVersion);
                        }
                    }
                }
            }
            _productVersions = packages;
            return _productVersions;
        } catch (SecurityException e) {
            return NSDictionary.EmptyDictionary;
        }
    }

    // Make product versions dictionary more readable by alphabetizing by
    // package name and writing each package on its own line.
    public static String formattedDictionary(NSDictionary aDict) {
        String packageVersionString = aDict.toString();
        packageVersionString = packageVersionString.substring(1,
            packageVersionString.length() - 2);
        NSArray packageStrings =
            NSArray.componentsSeparatedByString(packageVersionString, "; ");
        try {
            packageStrings = packageStrings.sortedArrayUsingComparator(
                NSComparator.AscendingStringComparator);
        } catch (NSComparator.ComparisonException e) {
        }
        return packageStrings.componentsJoinedByString(";\\n");
    }
}
```

Usage

The _productVersions NSDictionary contains the following:

- The keys are the version strings for the different packages.
- The values are the packages for that version string.

Using the above code will generate the following output:

```
Version information:
{
    "DVDPlayerUpdate 3.1.1 (build 1B203)" = (DVDPlayerUpdate.pkg);
    "Epson Print Drivers 1.1 1.1 (build 4L13)" = (EpsonPrintDrivers.pkg);
    "Mac OS X 1.0 (build 5S66)" = (NetworkingUpdate.pkg);
    "Mac OS X 1.0 (build 5U6)" = (SecurityUpdateJuly2002.pkg);
```

iTunes 3: How to create CDs from Audible content

Learn how to convert Audible files and save them on an audio CD.
This article has been archived and is no longer updated by Apple.
iTunes 3 can play and use Audible spoken word files from Audible.com. Audible audio files are a proprietary audio format that use security technologies, including encryption, to protect purchased content. To understand how to use Audible files to burn audio CDs, it's important that you understand a number of limitations to their usage. Additional information is available by visiting to Audible's web site.

If you have a later version of iTunes, see "iTunes: How to create CDs from Audible content."

Limitations to Using Audible Audio

You can use iTunes 3 to listen to any Audible audio content, just like you would with any other audio or music file. Audible files can be organized into playlists or smart playlists. You can edit their ID3 tag information just like any other audio file. You can even provide a personal rating or an equalizer preset.

There are a few things you cannot do with Audible audio files.

- Audible audio cannot be converted to other audio formats.
- Audible audio cannot be used to create MP3 CDs.

If you try to convert an Audible file to a MP3 using the Convert Selection to MP3 command in the Advanced menu, the message "Audible files cannot be converted to other formats." appears.

If you try to burn an MP3 CD from a playlist that includes some Audible content, an alert box with this message appears: "None of the items in this playlist can be burned to CD."

You cannot burn Audible files to CD as MP3. You must burn them as AIFF or as audio CDs. Audible.com allows for a single set of audio CDs to be created from their purchased content.

Burning Audible Audio to CD

Burning Audible audio can be difficult, based on the large size of a lot of the files. Many of the audio files (like audio books) can be many hours in length. If you attempt to burn a CD from a file that is larger than the space available on the CD, an alert box with the message "One or more of the songs in this playlist will not fit on the CD." appears.

An audio CD is limited to 60 to 80 minutes of audio content. A basic recordable CD (CD-R) allows for 74 minutes of audio, but CD-R discs are available in lengths up to 80 minutes.

To burn Audible audio that is longer than one CD, you must segment the large file into parts that will fit onto multiple CDs.

Segmenting Large Audio Files

While the segment feature is not new to iTunes 3, it has not been widely used. To segment any audio file for burning, use the Start/Stop time control, located in the Song Information window for the file.

1. Select the Audible file from the playlist.
2. Choose Get Info from the File menu.

3. Click the Options tab to access the Start Time and Stop Time Fields.

Setting Start and Stop Time Fields

The Original Speeches AudioBook is 4 hours, 39 minutes and 11 seconds in length. You will need to set the Start Time and Stop Time for each CD you burn of this program, to create a complete set of CDs spanning the entire program. In this example you would need at least 4 CDs.

1. Find a natural break point in the AudioBook. Listen to audio content around the time you want to place the stop time. Ideally you want to find a natural pause such as the end of a sentence or word. Stop iTunes at this break and note the time displayed. This is the stop point for one disc and the start point for the next disc.

2. Enter the Start time. Going strictly by the time division, the first segment could be set to end after 74 minutes, or 1 hour 14 minutes.

3. Click Burn CD.

4. Insert a blank CD-R disc.
5. Click Burn CD.

6. Repeat steps 2 through 5 until the entire audio content has been saved on CDs. In the example, the second segment could be set to start at 74 minutes and end at twice that length (148 minutes), or 2 hour 28 minutes.

   The third segment could be set to start at 2 hours 28 minutes and end at 3 hours 42 minutes.

   The fourth, and final, segment could be comprised of the remaining time, starting at 3 hours 42 minutes and continuing until the end.

Apple II AppleShare Network: Troubleshooting Freeze-Ups

I have three AppleShare networks. One has all new Apple IIGS computers, and the other two are mixed with Apple IIe systems, plus both old and new Apple IIGS computers. They all come up fine but, two or three hours later they freeze. When we restart the computers most (not always the same ones) freeze at the IIGS loading gauge. This happens only on the new IIGS models.

I have about thirty Apple networks installed. On some of them, new Apple IIGS computers froze from the beginning. Replacing their logic boards seems to fix the problem. However, on the last one, the problem just moved to another, previously "clean" computer.
This article has been archived and is no longer updated by Apple.
First, check for bad RAM, the most common cause of a system locking up during startup. This would explain why swapping logic boards cured the one case.

Second, check for bad software on server. In this case, this diagnosis is more likely, because the condition is appearing on more and more systems. Try re-installing the server, making sure you use the Network Products Installer disk.

Re-install the following:

1) System 6.0.5

2) AppleShare 2.0.1

3) AppleShare Apple II Setup 2.1.1

4) GS/OS 5.02

.Mac Backup: "Cannot Connect to .Mac to Verify Your .Mac Membership" Alert

.Mac Backup cannot connect to verify .Mac membership if your computer is on a network that uses a proxy server.
This article has been archived and is no longer updated by Apple.

Symptom

When you open Backup, an alert box appears with a message that says the application could not connect to .Mac to verify your .Mac membership.

Solution

Move the computer you want to back up to a place where proxy severs are not required. Backup 1.0 and later cannot be used with proxy servers.

The first time you open Backup your .Mac account is verified, which is why the computer needs to be located outside of proxy servers. After your membership has been verified, you can change the backup destination to CD/DVD. The next time you open Backup, the authentication process is not required. You don't even need to be online to back up to CD/DVD.

Note: When opening Backup after the first authentication, you will see an alert box with this message: "iDisk Server is Unreachable. The iDisk server is either unavailable or unreachable. Please try again later." The options are to select "Open Network Prefs" or "OK". If you click "OK", Backup will open with CD/DVD selected as the backup location.

Apple Remote Desktop 1.1: About Copying Invisible Files

This document describes how Apple Remote Desktop copies invisible files by when you use the Copy Hard Disk command on a Mac OS 9 volume.

This article has been archived and is no longer updated by Apple.

The Copy Hard Disk command in Apple Remote Desktop 1.1 can copy the contents of a local volume to a remote computer. However, Apple Remote Desktop does not copy invisible files and folders at the root (top) level of the hard disk. This includes the Mac OS 9 Desktop Folder, Trash, Temporary Items folder, and other invisible items. Invisible files and folders located elsewhere on the hard drive, however, can be copied using Apple Remote Desktop.

WebObjects 4: Issues with Applications Using Enterprise Objects from Multiple Threads

Objective-C applications written for WebObjects 4.0 and WebObjests 4.5 that use the Enterprise Objects Framework from more than one thread and whose threads do not run indefinitely may on rare occasions raise exceptions, damage memory, and cause memory faults.
This article has been archived and is no longer updated by Apple.

Symptoms

- exception "enableObserverNotification called when not supressed"
- damage to a random memory location
- memory faults

These symptoms may occur very rarely, and a given application may exhibit different symptoms at different times.

Solution

1. Add to your project a file EOFThreadWorkaround.h containing the following:

```
//  EOFThreadWorkaround.h
//  Copyright (c) 2002 Apple Computer, Inc. All rights reserved.

#import <EOControl/EOControl.h>

@interface EOObserverCenter (ThreadWorkaround)

//  preventCertainExceptionsOnThreadExit -- Invoke this once, at startup, before doing any EOF operations, to work
//  around certain problems with multi-threaded EOF applications.

+ (void) preventCertainExceptionsOnThreadExit;

//  changeThreadCache -- Any thread which does EOF operations but which is NOT created with NSThread should
//  invoke this just before exiting.

+ (void) changeThreadCache;

@end
```

2. Add to your project a file **EOFThreadWorkaround.m** containing the following:

```
//  EOFThreadWorkaround.m
//  Copyright (c) 2002 Apple Computer, Inc. All rights reserved.

#import "EOFThreadWorkaround.h"

@implementation EOObserverCenter (ThreadWorkaround)

static NSConditionLock  *threadFixLock = nil;

//  Conditions for the above lock
#define CONDITION_VALID             1         // idle state
#define CONDITION_NEEDCHANGE        2   // need some other thread to change the cache for us

+ (void) _changeThreadCacheWhenNeeded;
{
     [[NSAutoreleasePool alloc] init];

     //  Loop forever, waiting for other threads to signal that they need the cache changed.
     //  When they do, query the suppress count, which gets OUR thread into the cache.
     //  Since our thread stays valid forever, this makes the cache valid, important when
     //  other threads are exiting.

     while (1)
     {
          [threadFixLock lockWhenCondition: CONDITION_NEEDCHANGE];    // wait 'til we're needed
          [EOObserverCenter observerNotificationSuppressCount];
          [threadFixLock unlockWithCondition: CONDITION_VALID];       // and tell the world we're done
     }
}

+ (void) preventCertainExceptionsOnThreadExit;
{
     static BOOL beenHere = NO;
```

```
    if (beenHere) return;                                       // do this only once
    beenHere = YES;

    //  Create the lock to let any thread communicate with the cache-fixing thread
    threadFixLock = [[NSConditionLock alloc] initWithCondition: CONDITION_VALID];

    //  Spawn the cache-fixing thread
    [NSThread detachNewThreadSelector :@selector(_changeThreadCacheWhenNeeded)  toTarget: self  withObject: nil];

    //  When any thread is about to exit, change the cache.
    [[NSNotificationCenter defaultCenter] addObserver: self
        selector:@selector(changeThreadCache)
        name:NSThreadWillExitNotification
        object: nil];
}

+ (void) changeThreadCache;
{
    //  Grab the lock so we know the other thread isn't in the middle of things
    //  Then unlock it, to make it do its change-thing
    [threadFixLock lockWhenCondition: CONDITION_VALID];             // wait 'til we can jump in
    [threadFixLock unlockWithCondition: CONDITION_NEEDCHANGE];      // and tell helper thread to do its thing

    //  Wait for it to do its thing
    //  Then unlock it without changing things
    [threadFixLock lockWhenCondition: CONDITION_VALID];             // wait for it to do its thing
    [threadFixLock unlock];
}

@end
```

3. Change your application to include the following, invoking the method only once at startup (in the main() function or in your application's initialization):

```
#import "EOFThreadWorkaround.h"
...
[EOObserverCenter preventCertainExceptionsOnThreadExit]; // one-time code to set up workaround
```

4. If your application or any third-party libraries in your application spawn any threads that use EOF but do not exit with [NSThread exit], invoke the following method just before exiting the thread.

```
[EOObserverCenter changeThreadCache]; // make sure our thread isn't in EOF's cache
```

This step is critical to working around the problem -- step 3 covers only threads that exit with [NSThread exit], but you must make sure that every thread that uses EOF is corrected. This step handles threads that do not exit with NSThread's method.

Power Mac G4 (Mirrored Drive Doors): Only Insert Headphones into the Sound Output Port

A set of headphones is the only device that should be inserted into the sound output port on the front of the computer.
This article has been archived and is no longer updated by Apple.
Only headphones should be plugged into sound output port on the front of the computer. All other audio devices should be connected to the sound output port at the rear of the computer.

Note: If headphones are connected through audio devices, such as grounded speakers, or mixers, and these devices are connected to the headphone sound output port, you may hear fan interference through the headphones.

LaserWriter IINT/IINTX: Symptoms of Badly Mounted Power Supply

On power up, the LaserWriter IINT/NTX Ready light blinks, then the Toner light comes on solid. Shortly after this, both the Ready and Toner lights go solid, and the printer fails to generate a user self-test page. Subsequent service self-tests generate only blank pages.

This article has been archived and is no longer updated by Apple.

These symptoms appear when the high-voltage power supply is incorrectly mounted with connector pins (to the DC Controller) completely missing their places. This only happens during a repair, when the high-voltage power supply is replaced.

Mac OS X Managed Client: Computers Do Not Show Full List of Users

Workgroup Manager client computers that are set up to get their configuration from a Managed Client Server (Mac OS X Server 10.2 or later) and show a list of users, may not show all the user accounts that exist in the server's database if the preferences are not defined.
This article has been archived and is no longer updated by Apple.

Symptom

Workgroup Manager client computers that are set up to get their configuration from a Managed Client Server (Mac OS X Server 10.2 or later) and show a list of users, do not show all the user accounts that exist in the server's database.

Solution

The list of computers in Workgroup Manager must be set to "Define" for the affected group of computers. By default, Workgroup Manager only has a Guest computer list, and preferences are not defined.

1. Open Workgroup Manager.
2. Click the Computers tab.
3. Either set up a specific group of computers, or use the Guest computer setting.
4. Click the desired computer list.
5. Click the List tab.
6. Click Define.
7. Click the Access tab. You may choose to allow all groups to use the computer, or you can restrict only certain workgroups to the list.

ProDOS: Setting the prefix before using the CONVERT Program

The ProDOS User's Disk, /USERS.DISK, contains a CONVERT Program that transfers DOS files to ProDOS disks.
This article has been archived and is no longer updated by Apple.
For these transfers, users must remember to set the ProDOS prefix (in this case, volume name) to the prefix of the disk to which they want to send files. The ProDOS prefix defaults to the prefix of the startup disk (/USERS.DISK in this case).

At the beginning of the transfer, the system checks for the correct type of disk (ProDOS or DOS 3.3) and the prefix of the ProDOS disk; if you've forgotten to change the profix, you will receive the message "No Room on Volume" (namely, /USERS.DISK).

Select option "P" from the CONVERT main menu, change the prefix, and all will be fine.

A Tip: Writing the volume name on the label of each of your ProDOS disks will help you to remember that you must provide CONVERT with the disk's prefix.

iPod for Windows: How To Contact MUSICMATCH Technical Support

This document contains instructions for contacting MUSICMATCH.
This article has been archived and is no longer updated by Apple.
Important: The contents in this document come solely from MUSICMATCH. Apple Computer is not responsible for the contents of this document, nor does it claim any copyright on the information. All references to "we" in this document refers to MUSICMATCH.

The most current version of this document can be found at: http://wwws.musicmatch.com/faq/MISC020.htm

Note: All support offered by MUSICMATCH is available in English only.

MUSICMATCH Jukebox Technical Support by phone

Because we often need additional system configuration information emailed to us and the time involved in downloading new drivers or other files, MUSICMATCH does all technical support through email. We will be more than happy to assist through email but do not handle technical support by phone. We apologize for any inconvenience this may cause.

Regarding technical support issues, MUSICMATCH Jukebox is capable of providing detailed diagnostics regarding its installation and configuration on your PC. This information can help us better and more quickly identify the source of the problem you may be experiencing and allow us to better suggest a solution. Please resubmit your issue by doing the following (If you have already included this information, please include it again in the diagnostic report submission. This will allow us to consolidate the details regarding your issue and avoid future duplicate requests and delays.):

1. Connect to the Internet.
2. Open MUSICMATCH Jukebox.
3. Within MUSICMATCH Jukebox, click the Help menu, then Request Technical Support.
4. Under "Describe your PC System", please include the details about your system listed under "PC DESCRIPTION" below.
5. Under "Give a detailed account of the problem that you are seeing", please include answers to the QUESTIONS section at the bottom of this message.
6. Enter your email address and name into the spaces provided.
7. Place a check in each of the checkboxes under "Files", and select "Yes" under "Would you like to send this information to MUSICMATCH now?"
8. Click the OK button.

If you are unable to open MUSICMATCH Jukebox, these diagnostics are stored in separate files that you can attach to a reply to this message to provide us with much of the same information. Please attach the following files to your reply:

USERINFO.DAT
MMJBLOG.TXT
ALTLOG.TXT
MMJBREC.LOG
MMJB.RPT
MMCD.INI
MMJBLOG.SAV

These files will be found in your MUSICMATCH Jukebox installation directory if they exist (some of the files may not be present if they have not yet been created by the application). By default, the installation directory is "C:\\PROGRAM FILES\\MUSICMATCH\\MUSICMATCH JUKEBOX\\", but this path will be different if you specified a custom directory when you installed MUSICMATCH Jukebox.

If you are unable to open MUSICMATCH Jukebox, please also do the following to find out what exact version of MUSICMATCH Jukebox you are using:

- Open Windows Explorer.
- Navigate to the MUSICMATCH Jukebox directory.
- Right-click on MMJB.EXE
- Select "Properties".
- Click the "Version" tab.
- Under "Item name", click "Product Version".
- Include the number in the "Value" box with your reply (please include any three-letter extensions).

Please include the PC description details and answers to the questions listed below.

PC DESCRIPTION:
- Processor type and speed.
- Amount of RAM installed.
- Manufacturer and model of sound card.
- Any additional details you feel may be important.

QUESTIONS:
- Please include a detailed description of the trouble you are experiencing, including the following:
o A description of what you are trying to accomplish with MUSICMATCH Jukebox.
o The exact steps you are taking leading up to the problem.
o The exact point at which the trouble occurs.
o How often the problem occurs.
o The exact text of any error message you are receiving. If a "Details" button appears with the error message, please click it and include this exact text as well.
- Are you logged in to your computer as an administrator, power user, regular user, or other (please specify)?
- What applications are you running in the background or in the system tray (next to the clock in the Windows Taskbar)?
- Is this the first time you have installed MUSICMATCH Jukebox, did you install over a previous version using a setup file you downloaded from our web site, or did you use the Update Software feature inside the Options menu of MUSICMATCH Jukebox?
- If you updated from a previous version of MUSICMATCH Jukebox, did this problem first occur right after your update?
- Copy the unique tracking number at the bottom of this email and paste it into the support request form.

Again, this information can help us better and more quickly identify the source of any problem you may be experiencing and allow us to better suggest a solution.

Power Mac G4 (Mirrored Drive Doors): Balanced or Grounded Equipment Has a Humming or Buzzing Noise

This document describes how to eliminate audio buzzing or humming noise coming from the audio sound output port.
This article has been archived and is no longer updated by Apple.

Symptom

Balanced or grounded audio equipment connected to the audio sound output port has a humming or buzzing noise.

Solution

Connect the line output of the Power Mac G4 to the input of a stereo isolation transformer, and connect the output of the transformer to the audio equipment. Isolation transformers (also known as "ground loop isolators") are typically available at professional home/car audio retailers.

Additional information

Audio Equipment

There are two types of audio equipment that have two different types of inputs and outputs. Professional equipment, which uses balanced inputs and outputs, and consumer equipment, which uses unbalanced inputs.

Unbalanced Inputs and Outputs

Most of the common audio and video equipment you own has one of two types of connectors; coax connectors, also referred to as RCA connectors, and 3.5 mm connectors, also referred to as 1/8-inch connectors. Both of these types of connectors have only two lines per channel: the wire that carries the audio signal, and the shield or ground. 3.5 mm connectors usually contain a pair of wires and one shield, thus providing left and right stereo in a single cable. However, the 3.5 mm cable still only provides one wire and shield per channel. The shield on these types of cables are shared between the left and right audio wires. These two types of connectors make up most of the audio and video connectors found on common multimedia equipment.

The Power Mac G4 (Mirrored Drive Doors) is designed to integrate with your existing multimedia equipment. As such, it uses unbalanced inputs and outputs. This means it works out of the box with most stereo equipment, televisions, VCRs, and portable speakers.

Balanced Inputs and Outputs

Professional multimedia equipment uses a different connector called an XLR connector. It consists of three wires/pins for each channel. Two wires contain an equal voltage signal, which carries the audio. The third wire contains the ground. In most cases this style connector is not used on your audio and video equipment. In addition to having the specialized XLR connector, equipment with balanced inputs and outputs work on a different signal level than consumer equipment with unbalanced lines.

The Power Mac G4 (Mirrored Drive Doors) does not use XLR connectors, nor does it provide the proper signal level for balanced equipment without additional add-on hardware.

Using the Power Macintosh with Balanced Equipment

When balanced or grounded audio equipment is connected to the sound output port on the Power Mac G4 (Mirrored Drive Doors) computer, you may hear a humming or buzzing noise. This is caused by what is known as a ground loop.

Ground loop issues are usually completely eliminated if a stereo isolation transformer is used. An isolation transformer isolates the electrical grounds of two pieces of audio equipment and only allows audio signals to pass through.

Macintosh Nubus Cards: Effect on Power Supply

Is there a problem with putting three or more NuBus cards in a Macintosh II family system?

This article has been archived and is no longer updated by Apple.

Not inherently, but the more cards you install, the greater the drain on the power supply. If the power supply was bad, it might not show up until it was under this increased load. Some card makers don't follow Apple specifications about power draw per card. Out-of-spec cards can strain the power supply.

iMovie: "Could not find the language resource file" Alert

If you try to open an iMovie project in Mac OS 9 using the Mac OS X version of iMovie, an alert box with an error message appears on the screen.
This article has been archived and is no longer updated by Apple.

Symptom

When you double-clicking an iMovie project file in Mac OS 9, an alert box with this message appears:

> "Could not find the language resource file, please reinstall the application."

Solution

By default, iMovie 2 for Mac OS 9 Mac OS X are both installed on the hard disk.

Since iMovie 2 for Mac OS X is more recent, the Mac OS 9 Finder tries to open the iMovie file using iMovie 2 for OS X. This version of iMovie is
not designed to work with Mac OS 9. If you try to open the file using iMovie 2 for Mac OS X this alert box appears.

To open the file in iMovie 2 using Mac OS 9, do one of the following:

- Open the iMovie 2 for Mac OS 9 application first.
- Drag the iMovie project file onto the iMovie 2 for Mac OS 9 application.
- Open the project file from within the iMovie application.

For more information about the order in which applications open under Mac OS 9, see technical document 17713, "**Finder Search Path for Applications**".

32-Bit QuickDraw and Print Monitor Problem

I have a Macintosh IIx with 8MB of RAM, an 80MB hard disk, and a 24-bit video board. I am running System 6.0.4 with MultiFinder and 32-bit QuickDraw active. I am trying to print using the background printing option. When I try to print a 24-bit image, the program quits with a MultiFinder 01 error (a bus error, I believe), but not until it has already fed the print job to the print monitor. I have noticed this from Pixel Paint Professional, Microsoft Word 4.0, and other programs.

I have completely trashed my System Folder twice to no avail. However, if I disable background printing, it works fine (no MultiFinder 01 bombs). The only thing that does not seem to work properly is the memory allocation to the print monitor. No matter what I set it to, it seems to take the "recommended" amount of memory, rather the allocated amount.

Do I have a bad copy of the System disks? Would you update to System 6.0.5 solve the problem? Do I need LaserWriter 6.0.1 to print 24-bit images to the NTX (or should 6.0 work?)

This article has been archived and is no longer updated by Apple.
We recommend upgrading to 6.0.1 LaserWriter and Laser Prep, so that you are using the most current drivers. You should also have Color/Greyscale selected in the Print dialog box.

There is a possibility that you are running the Installer (we hope you are using the Installer) from damaged diskettes. If you have a known-good locked set, throw away your System Folder and use these good disks to reinstall by running the Installer.

Power Mac G4 (Mirrored Drive Door): QuickTime Movie Has Purple or Green Tint

The Power Mac G4 (Mirrored Drive Door) computer may display incorrect colors when playing QuickTime content, and in QuickTime-based applications.
This article has been archived and is no longer updated by Apple.

Symptom

QuickTime movies have a purple or green tint to them. Applications that use QuickTime such as Final Cut Pro, DVD Studio Pro, iMovie, iDVD, and Preview also have a green or purple tint.

Solution

Download and install Mac OS X 10.2.2 or later. It is available in the Software Updates pane of System Preferences, or from Apple Software Downloads (http://www.apple.com/swupdates/).

TA46201_AppleShare_Server_Performance_and_RAM_(TIL07543).pdf

AppleShare Server: Performance and RAM

Would the performance of a Macintosh SE/30 server improve with more RAM installed?

This article has been archived and is no longer updated by Apple.

Additional memory in the server would provide only a small increase in performance, probably less than the relative cost of the memory. In the server. Memory only allows more simultaneous users with little effect on performance.

iTunes 3: Playback Device Compatibility

This document contains the iTunes device compatibility as of 2004-01-19.
This article has been archived and is no longer updated by Apple.

Playback Device Compatibility

MP3 players

Enjoy your MP3s on the go. It's easy with iTunes 3. Connect your MP3 player to your Mac and its icon appears in the iTunes window. Just drag tracks to it from your library or playlist, and you're ready to hit the road. iTunes 3 supports today's most popular USB and Firewire based MP3 players.

The iPod is the perfect companion to iTunes 3. Small enough to fit in the palm of your hand yet big on performance, iPod holds over 4,000 songs and syncing a CD's worth of music takes only seconds with FireWire.

MP3 Players	Manufacturer	Format
iPod	Apple	FireWire
Nomad II	Creative Labs	USB
Nomad II MG	Creative Labs	USB
Nomad II c	Creative Labs	USB
Nomad Jukebox	Creative Labs	USB
Nomad Jukebox 20GB	Creative Labs	USB
Nomad Jukebox C	Creative Labs	USB
Rio One	SONICBlue/S3	USB
Rio 500	SONICBlue/S3	USB
Rio 600	SONICBlue/S3	USB
Rio 800	SONICBlue/S3	USB
Rio 900	SONICBlue/S3	USB
psa]play 60	Nike	USB
psa]play 120	Nike	USB
SoundSpace 2	Nakamichi	USB

CD MP3 Players

iTunes has built-in support for CD MP3 players.

CD MP3 Players	Manufacturer
RioVolt SP250	SONICBlue/S3
RioVolt SP100	SONICBlue/S3
RioVolt SP90	SONICBlue/S3

FireWire and USB CD-R Compatibility

Making Custom CDs

Using iTunes 3 Mac OS X you can create (or burn) custom audio CDs which are playable in your car, portable CD player and home stereo system using iTunes. You can also make custom MP3 CDs, standard audio CDs and data CDs directly from the Finder.

Using FireWire and USB external drives

While running Mac OS X you can create CDs using many FireWire and USB external media burners. For better performance and reliability, use FireWire drives.

To see if your drive is supported, open iTunes then choose Preferences from the Edit menu. Click the Advanced icon. In the CD Burning section of the Preferences window, check to see if your drive is listed. If it is listed then your Macintosh recognizes and works with your drive and you can use it to burn CDs. For more information about identifying the firmware and mechanisms of your drive, see the Apple Knowledge Base article: How to Determine an Optical Drive's Mechanism and Firmware Version.

FireWire, USB, and USB 2.0 drives tested with iTunes

TA46203_iTunes_Playback_Device_Compatibility.pdf

Below is a list of drives and their corresponding mechanisms and firmware that support CD burning on Macintosh computers running Mac OS X. Some drives do not reliably play music or import songs into MP3 format. You may find that using the built-in CD/DVD drive or SuperDrive works better for these tasks.

Drive compatibility may vary due to manufacturers' use of multiple mechanisms or firmware versions in the same product. This compatibility list includes only those combinations tested by Apple.

WebObjects: How to Upgrade a Deployed WebObjects Application Running in a Production Environment

This document explains how to upgrade a currently deployed WebObjects application with a new version in a production environment.

The process described in this document allows the current version to continue running and processing requests while the new version is installed and brought online. This process is valid for WebObjects 4.5.1 and all versions of WebObjects 5.

Note: This document assumes you are using JavaMonitor and wotaskd to deploy and manage production applications.

This article has been archived and is no longer updated by Apple.
Important: The steps outlined in this document do not cover the situation where the new WebObjects application needs to modify or access the same files as the current version, nor does it cover situations when there is an update to the database. If you have schema or other database changes it may not be feasible to do an in-place upgrade of your application.

Add new instances of your new application

Use the same name, but place the new application in a different path from the current application so it does not generate a name conflict.

1. In JavaMonitor, click the Applications tab

2. Click Config next to your application.

3. Change the Path variable to point to the new version of your application executable.

4. Deselect the AutoRecover option.

5. Select Update for new instances only.
Important: Do not click "Push" or "Push All" as this attempts to modify the currently running version of your application.

6. Make any other changes you feel are necessary to your environment in the other application categories (such as Application Settings).

7. Open the Detail View by clicking Detail View in the upper right corner of the page

8. Add the appropriate number of instances of your new application. Be sure you add them to the correct host if you have more than one configured.

Prepare your earlier application so it can be taken offline

1. In Detail View, of the application tool, turn AutoRecover to OFF on the earlier instances of your application.
This ensures that when you shut these instances down wotaskd won't try to automatically restart them.

2. Turn on Refuse New Sessions on your older instances.
This allows your application to continue processing any current sessions, but they will refuse to accept any new ones.

Bring the new instances online

1. In Detail View start the new instances of your application by clicking the green button to the right of each new instance

When the new instances come online they will begin processing any new requests while the old instances complete their current sessions, or time out.

2. To add a level of robustness to your deployment you should turn AutoRecover back on for your new instances. This tells wotaskd to restart your instances in case they should go offline unexpectedly.

Shut down the old instances

1. Click the Red Light next to each instance to stop it when it no longer has any active sessions.
You can see the number of active sessions per instance from the application's "Detail View".

2. Delete the old instances after they all have stopped.

If there are issues when both versions of the application run at the same time, you need to bring the new instances online after you shut down the old instances.

AppleWorks 6: Intersheet Cell References Are Not Auto-Calculated

Spreadsheet cells in AppleWorks 6 that contain references to cells of other spreadsheet documents (intersheet cell references) are not auto-calculated. Use the Calculate Now command to ensure your spreadsheet information is up to date.
This article has been archived and is no longer updated by Apple.

Symptom

When changing a spreadsheet that contains cells referenced from another spreadsheet, the referenced cells are not updated in all spreadsheets.

Solution

Use the "Calculate Now" command when using intersheet cell references to ensure that the spreadsheet is up to date.

1. Open the AppleWorks spreadsheet containing the intersheet cell references.
2. Choose Calculate Now from the Calculate menu.

For more information about spreadsheet cell references, see "About spreadsheet cell references" in AppleWorks help, or in technical document 50343.

Macintosh to VAX Connectivity and Fatal Error 1020

Article Change History

02/08/93 - RETITLED
* To accurately describe the article.

I am having problems with my Macintosh Plus (System version 6.0.4) communicating with our VAX system. We are using PacerLink 5.3 for VAX access via AppleTalk (Fastpath access onto fiber-optic Ethernet backbone). My Macintosh occasionally freezes, forcing me to turn it off to reboot. Today, I got a dialog box that told me I had a Fatal Error #1020. According to the (somewhat sketchy) information I have, that should indicate an AppleTalk problem.

What specifically does that error indicate, and where should we concentrate our search for the source of the problem?

This article has been archived and is no longer updated by Apple.
If there are other users in your general area, follow these diagnostic steps:

1) Start by taking the Macintosh over to one of those network connections and see if the same problem occurs. If it does not occur there, verify the connection at the original location. If so then continue with the next suggestions.

2) Check out the software at the Macintosh end. If possible, try another user's software (or hard disk with the software on it), so you can identify whether or not you have a software problem.

If other users are not experiencing the same problem, the network is not at fault. Our guess is that it's a software problem at your machine either in Pacer (likely) or in the System software (doubtful).

DVD Studio Pro: DVD-Video Disc Cannot Be a Multiformat (NTSC/PAL) Disc

This document explains why you cannot create a multiformat disc when using DVD Studio Pro.
This article has been archived and is no longer updated by Apple.
Warning: Using an incompatible video standard with your television set could damage it. You should note on the label of your completed DVD-Video which video standard was used (NTSC or PAL).

The DVD-Video specification does not allow for the creation of a multiformat DVD. You must create a separate project for each video standard.

It is possible to bring PAL video into an NTSC project and visa versa. However, if you burn a disc as NTSC and the project contains PAL formatted video, the PAL formatted video will not display on an NTSC television.

In addition, when you set a startup action, make sure the startup action is the same format as the project.

Note: The DVD-Video specification was written and is now maintained by the DVD Forum working group WG1, which comprises a number of task groups concerned with both read-only and recordable disc formats.

WebObjects 5.2: How to Prevent a Deadlock When a Direct Action Raises an Exception

If a Direct Action loads a session, then throws an exception, the WebObjects application stops responding ("hangs") the next time that same session is accessed.
This article has been archived and is no longer updated by Apple.

Symptom

If a Direct Action loads a session, then throws an exception, the WebObjects application stops responding the next time that session is accessed. Normally, the WOException page should return. However, it appears as if the link to the Direct Action is clicked and the application never returns. The application stops responding immediately if the concurrent request handling flag is disabled, or eventually, if the concurrent request handling flag is enabled.

The client browser would time out and show the message "No instance available" instead of the exception page.

Solution

The workaround is to manually present the exception page instead of depending on WebObjects to present the default WOException page when an exception is raised.

In the WOApplication subclass, override the `handleActionRequestError` method as follows:

```
public WOResponse handleActionRequestError(WORequest aRequest, Exception exception, String reason,
WORequestHandler aHandler, String actionClassName, String actionName, Class actionClass, WOAction
actionInstance)

{
   return handleException(exception, actionInstance.context());
}
```

WebObjects 5.2: Project Builder 2.1 Debugger Breakpoints Ignored

The debugging of WebObjects Java code under Project Builder does not break at breakpoints.
This article has been archived and is no longer updated by Apple.

Symptom

After setting one or more breakpoints in Project Builder, debugging the project does not result in execution breaking at any of the breakpoints. This symptom may not be limited to only WebObjects projects. This symptom occurs because Project Builder does not always default to the correct debugger.

Solution

For each WebObjects executable Java project (WebObjects application) created using an earlier Project Builder version and for each new executable WebObjects Java project, do the following:

1. Build the project.
2. Click the Project Builder Targets tab.
3. Click the Executables disclosure triangle and select the executable file to be debugged.

4. In the Targets template, choose Debug Action from the Configure pop-up menu. This is located in the Launch Configuration section towards the bottom.
5. Choose Java Debugger from the Launch using pop-up menu.

AppleTalk: How to Upgrade to Phase 2 to Use PATHWORKS

We need to upgrade our AppleTalk network to Phase 2 to use PATHWORKS. Our network consists of six zones, five are separated by Shiva NetBridges, while the other is separated by Cayman GatorBoxes. From what I've read, it looks like all I need to do is set the GatorBoxes to AppleTalk rout using Phase 2 instead of Phase 1 for us to be "upgraded." This sounds a bit too easy.

What else do I need to do? Currently, the only other devices we have are Macintosh computers, LaserWriter printers, some NetSerials and NetModems, and a Netway.

This article has been archived and is no longer updated by Apple.
Easy is what Macintosh is all about! Phase 2 has to be implemented on routing devices, so the GatorBox and the Shiva NetBridges also need upgrading. Check with Shiva on their plans or procedure for upgrading the NetBridge to Phase 2. That is basically all there is to it; the computers on the network have no requirement for an upgrade to Phase 2.

iMovie 3: Some Graphic Files Import as Blank (White) Clips

Graphic files in PICT format that you import into an iMovie 3 project may appear as blank, white clips in the timeline after rendering is complete.
This article has been archived and is no longer updated by Apple.

Symptom

After placing a PICT format picture into the iMovie project timeline, the photo renders and turns into a blank, white clip.

Solution

1. Use Preview, iPhoto, or another application to export or convert the PICT format picture to another format such as JPEG or TIFF.
2. Import the JPEG or TIFF image into the iMovie 3 project instead of the PICT file.

This document may be updated as more information becomes available.

iPod: Learning More, Support, and Service

This document describes where to get more information and help with the iPod.
This article has been archived and is no longer updated by Apple.

Online Help

Comprehensive help for iPod is included with iTunes. Choose Help > iPod Help.

Knowledge Base

The Knowledge Base (http://kbase.info.apple.com/) contains support information for all Apple products and is constantly updated to include the latest information.

Apple Websites

Additional support and troubleshooting information is available from Apple Web pages.

iPod Page - (http://www.apple.com/ipod).

iPod Support Page - (http://www.info.apple.com/usen/ipod/)

For international support, go to (http://www.apple.com/support/) and choose your country from the pop-up menu at the bottom of the screen.

Obtaining Warranty Service

If the product appears to be damaged or does not function properly, follow the advice in the iPod manual, the onscreen help, and the online resources.

If iPod still does not function, go to (http://www.apple.com/support/) for instructions on how to obtain warranty service.

Communications regulation information

For information on communications regulations, see the file on the iPod CD.

LaserWriter: How to Upgrade Drivers on an AppleTalk Network

All LaserWriter drivers must be exactly the same on an AppleTalk network in order to prevent printer reinitialization every time someone prints. On the other hand, you can use any version printer driver with any version of System 6.x.x software. So if five people were running SEs with System 6.0.4 and LaserWriter driver 6.0, and a sixth machine running under System 6.0.5 (a IIfx, for example), the sixth machine could still run LaserWriter driver 6.0. (It's less hassle to make one adjustment than five.) Right?

Is there an enhanced functionality to LaserWriter driver 6.0.1, so that to get the absolutely best results, it would be best to upgrade the 6.0.4 SEs over to LaserWriter driver 6.0.1?

This article has been archived and is no longer updated by Apple.
Yes. You are correct in your first paragraph above, and if there is a new LaserWriter/Laser Prep file introduced you should be able to upgrade to that driver with no other system upgrade, unless it was so specified.

There was an upgraded Print Monitor with the 6.x drivers. Version 1.3 was distributed with the System 6.0.5 suite of diskettes while version 1.2 was distributed with the System 6.0.4 suite of diskettes. The 1.3 version would probably contain the enhancements necessary for use with any of the current printer drivers.

Xserve (Slot Load): Gigabit Ethernet Card Not Reported Correctly in Apple System Profiler

Information about the server's Gigabit Ethernet PCI card may not be reported correctly in Apple System Profiler.
This article has been archived and is no longer updated by Apple.

Symptom

Incorrect information about the server's Gigabit Ethernet PCI card appears in Apple System Profiler. Instead of Card Type, Card Name, Card Model, Apple System Profiler displays nondescriptive numbers, or the information is missing as "Not available".

Solution

This is a known issue with Apple System Profiler. It does not indicate that the Ethernet card is malfunctioning.

iDisk: About .HSicon Files

This document discusses the .HSicon files that you see when connecting to an iDisk from a Windows-compatible computer, computers with a UNIX-style operating systems, or from the Terminal application in Mac OS X.
This article has been archived and is no longer updated by Apple.
Important: Do not delete the .HSicon files.

There are two .HSicon files on your iDisk. They are located at the root level and in the Public folder.

The .HSicon files show the images of an iDisk or an iDisk Public folder when connected using AFP (Apple Filing Protocol) in Mac OS 9. If you delete the .HSicon file in the Public folder, it will not have the right icon when you connect to it using AFP in Mac OS 9.

Data General: Terminal Line Dropped for Macintosh

I have a Macintosh IIci with a 40MB internal CMS drive with 4MB RAM. It replaces a Data General terminal. It's connected to our terminal line (DB-25 male) using a female-to-female gender changer and an Apple IIe/ImageWriter II cable (third-party) connected through the modem port.

Thus, I use my Macintosh part-time to communicate with a Data General (Versaterm does the DG emulation). Communication works flawlessly, and everything else is fine until I shut down the Macintosh at the end of the day. When I turn on the Macintosh in the morning, the DG has disconnected the line. I have to contact our systems people and have the line reconnected. Apparently the DG is polling the lines at night and something is timing out and disconnecting them.

I disconnected the cable from the back of the Macintosh at night, and everything works fine when I reconnect it in the morning. Note: People can shut off their terminals at night without the line being disconnected. However, I don't want to unplug the cable from the Macintosh every night.

Is the Macintosh doing something out of the ordinary with the serial ports when the machine is off?

This article has been archived and is no longer updated by Apple.
We suspect the cable may have a pin jumpered in it that may be causing this problem when the mainframe polls the Macintosh in the evening. The possibility is that pins 6 and 8 (jumpered), which should go to 20 on the DG, may be pulled down signal-wise and responding as if the connection is gone. This closes the line for security at the mainframe.

When the cable is disconnected from the Macintosh, those signals are cancelled, because there is not a continuous loop inside the serial port and the mainframe can tell that. When the cable is connected, it goes through the serial port and incorrect cabling may respond as if the connection has dropped.

We suggest you verify that the cable you are using is the correct configuration and not having any extra pins jumpered inside. When the Macintosh is off, nothing happens with the serial port (no power, no activity).

We cannot tell you if there is a way to have the mainframe discontinue the polling overnight. That may be one workaround besides verification of the cable.

iLife: QuickTime 6.1 Installer Is Not Included

The QuickTime 6.1 installer referenced by the iLife installer cannot be found on the iLife CD or DVD.
This article has been archived and is no longer updated by Apple.

Symptom

The iLife installer states a separate QuickTime 6.1 installation is included on the iLife discs.

Solution

QuickTime 6.1 is not included on the iLife discs. QuickTime 6.1 is available online using Software Update. Choose Apple menu > System Preferences, then choose View > Software Updates.

The latest versions of QuickTime and iLife are available in the Software Update pane of System Preferences. Updates for the applications that are part of iLife are available from the Apple Software Downloads website (http://www.apple.com/swupdates/).

iPod Software 1.2.6 Update Requires Additional Steps

The instructions provided with the iPod Software 1.2.6 Updater do not include all the steps required for installation.
This article has been archived and is no longer updated by Apple.

Symptom

The iPod Software 1.2.6 Updater cannot be installed according the instructions provided with the download.

Note: The English instructions provided on the software download page have been updated to reflect the additional steps required.

Solution

Follow these steps after you have downloaded the update:

1. Double-click the file named "iPod126.dmg". The iPod Software 1.2.6 Updater volume appears in the Finder.
2. Open the iPod Software 1.2.6 Installer. In Mac OS X it is called "iPod126.pkg". In Mac OS 9 it is called "Apple SW Install".
3. Select the startup disk as the destination. The installer copies the iPod Software 1.2.6 Updater folder to the Utilities folder and quits.
4. Connect iPod to your computer.
5. Open iTunes. iTunes updates iPod automatically. If this does not happen, use the manual process below.
6. When prompted, unplug iPod from the FireWire cable, then plug it back in to complete the update process.

Manual update

You can also update iPod by opening the iPod Software 1.2.6 Updater utility. See technical document 60944, "**iPod: How to Update**" for instructions.

iMovie 3: PAL Clips Cannot Be Reversed or Sped Up

You may see unexpected results if you reverse or speed up a PAL clip in iMovie 3.
This article has been archived and is no longer updated by Apple.

Symptom

Only the first few frames of a PAL clip play if you try to speed up or reverse the clip.

Solution

Update to iMovie 3.0.3 or later to prevent this issue (http://www.apple.com/imovie).

After updating, reapply any speed or direction changes in existing clips for accurate playback.

Note: This issue does not affect NTSC clips.

Responder, Background, & AppleTalk: Purpose in System Folder

I am having problems with System 6.0.5 bombing. What are the functions of Responder, Background, and AppleTalk in the System folder? Are they needed? Could they be the cause of my problems?

This article has been archived and is no longer updated by Apple.

```
* You can remove Responder if you are not using Inter*Poll for network
 troubleshooting.

* Backgrounder writes temporary files for background printing under
 MultiFinder.  Do not delete this file.

* AppleTalk is a patch to the AppleTalk that is in ROM. It is needed for
 the efficient use of any network device.  Do not remove it.

If you are having bomb problems, we suggest you start up from the System
Tools diskette, trash your current System folder, and use the Installer to
re-install the System folder.
```

Macintosh IIcx: Troubleshooting Startup Freezes (4/94)

I have an intermittent problem with my Macintosh IIcx. It freezes when I start it up.

The system does not have any INITs in the System Folder. I re-installed System software 6.0.5 using the Installer. The system has a Mac286 card and an Irma Link card in it with 5MB of memory. The system board, memory, and power supply have been replaced.

This article has been archived and is no longer updated by Apple.
To troubleshoot this problem follow these steps:

1) Remove the Mac286 and the Irma Link cards to isolate the problem to either the cards or the CPU.

2) Completely throw away the System Folder.

3) Re-install the System Folder from known-good, locked System diskettes.

4) If the problem persists, try swapping the keyboard, cable, and mouse.

5) Have a service provider run diagnostics to determine if there is a hardware problem.

TA46224_Macintosh_IIfx_Proper_Placement_of_SCSI_Terminators__(TIL07553).pdf

Macintosh IIfx: Proper Placement of SCSI Terminators (11/94)

When my Data Frame drive is the only device in the SCSI chain, my Macintosh IIfx starts up, but whenever I have another SCSI device attached, the system won't start. It doesn't matter whether the external SCSI is the drive or the scanner. The SCSI devices are all at different addresses and the external device on the end of the line has termination.

The Data Frame was checked out here on a Macintosh IIci with an external Rodime 140MB SCSI drive. I had no problems with this configuration.

This article has been archived and is no longer updated by Apple.
The only thing we are concerned with is the termination of both the internal drive and the external devices. The IIfx requires the use of the black terminator rather than the standard platinum-colored terminators of other Macintosh computers. This terminator is included with the IIfx in the finished goods box.

We would also verify that the SCSI filter is installed on the internal SCSI bus at the drive. This filter connects between the SCSI ribbon cable and the drive itself and provides some additional termination internal to the IIfx.

Aristotle: "error occurred in your user folder" Message

I have an AppleShare network with 20 Apple IIGS workstations. The network has experienced numerous problems this year. Today, while exiting AppleWorks, nine systems locked up and displayed this message:

An error occurred in your user folder: see the administrator

At the same time, five networked ImageWriter II printers locked up. One system in the middle of this line had no problems. When we tried to restart the workstations, some went into BASIC, and some displayed garbage. Now, all systems are totally down.

This article has been archived and is no longer updated by Apple.
Based on the error message, the problem seems to be on the server itself. Go into the users' listing and re-establish the preferences for the users. That may help, and avoid a time-consuming backup and reinstall.

If that does not cure the problem, go back to the most recent backup and restore that data. There may be a corruption within Aristotle itself. If a backup is not available, then recreate the Users and Groups files, and stop short of re-installing Aristotle.

Finally, if the problem still persists, re-install Aristotle and re-create the users and groups.

ImageWriter LQ: Printing on Entire Ribbon

I have an Apple ImageWriter LQ printer that prints only on the top portion of the black ribbon. According to the manual, the ribbon assembly should shift up and down for an even use of the black ribbon. When the printer is first turned on, the ribbon mechanism shifts down and stays there.

I discovered that when the ribbon is not in the printer, the assembly does shift. When should the shift occur with a black ribbon? What triggers the shift?

This article has been archived and is no longer updated by Apple.
The ImageWriter LQ with the 2.0 driver prints on all four bands of the ribbon on multi-page documents; it should use all bands equally. It moves up through the different bands on each page, so if you print multiple one-page documents, it may stay on the top band. Make sure that you do not turn off the printer between print jobs. This resets the ribbon to the top band.

LaserWriter Plus: Double-Blinking Status Light

I'm having a problem with a LaserWriter Plus (recently upgraded) connected to an IBM. The "Busy" status light sometimes has an uncharacteristic "double blink," as opposed to the normal "single blink" when processing jobs. Also, when PostScript jobs from some applications are completed, the status light does not turn off, but instead starts to "double blink." What does a "double blinking" status light mean?

This article has been archived and is no longer updated by Apple.
The double-blinking light is normal. In certain instances, the yellow light continues to flash, indicating it is processing a job. This is most evident when you do a manual feed and insert the paper before the red jam-light comes on. Also, if an end-of-page command is not sent when printing from an MS-DOS machine, the lights continue to flash.

LaserWriter: Shared by Macintosh, Apple IIe, and IBM PC

I want to connect Macintosh, Apple IIe, and IBM PC, so they can share a LaserWriter IINT. Can this be done? (No file sharing is required.)

This article has been archived and is no longer updated by Apple.
The AppleTalk LaserWriters were designed to be shared.

* Any Macintosh has AppleTalk built in.

* An Apple II needs the Apple II Workstation card and software to enable access to a networked printer.

* An IBM PC needs a LocalTalk PC Card and AppleShare PC to get onto the LocalTalk network to communicate with the LaserWriter.

Published Date: Feb 18, 2012

LaserWriter IINT: Problems Printing from WordPerfect

I have an IBM Model 60 server and two Model 70/386 workstations tied together with IBM Token-Ring hardware and cables. Server and workstations run IBM LAN Program 1.03 and LAN support program. WordPerfect 5.1 LAN version runs on the server. The workstations have devices attached to the serial ports. The server is connected to the LaserWriter IINT through a serial cable. The spooler runs on an IBM-LAN program. Our LaserWriter IINT is in standard LaserWriter mode, not Diablo mode.

Printing from WordPerfect (through the parallel port) works unevenly. After printing a while, it quits. I noticed that when I send a simple one-page document to the LaserWriter IINT, the green "working" light blinks for a couple of minutes and then goes out.

WordPerfect support told me to print a file called "ehandler.ps" (provided by WordPerfect) to the printer (from DOS). He said this would print error messages when a PostScript job did not work satisfactorily.

I sent the ehandler.ps file to the printer, and the job printed fine. Afterwards, a sheet printed that said "Error: timeout" and indicated that the command that had failed was "timeout." Although I can print one-page jobs okay, longer jobs don't print properly; they only generate an error sheet.

What do I need to set or change?

This article has been archived and is no longer updated by Apple.
We have three things for you to try:

1) Temporarily disable the spooler to see if there is a problem with the communication between it and the printer.

2) Verify the correctness of the cable. Here are the correct pinouts for both a DB-9 and DB-25 cable to the LaserWriter II.

IBM PC/AT LaserWriter
DB-9 DB-25
--- ---
(RXD) 2 ---------- 2 (TXD)
(TXD) 3 ---------- 3 (RXD)
(DTR) 4 ---------- 6 (DSR)
(SG) 5 ---------- 7 (SG)
(DSR) 6 ---------- 20 (DTR)

IBM RS-232 Serial (DTE) LaserWriter / LaserWriter Plus (DTE)
(DB-25 Female Connector) (DB-25 Male Connector)

2 ---------- 3
3 ---------- 2
5 ---------- 4
6 ---------- 20
7 ---------- 7

3) Verify that the LaserWriter's DIP switches are correctly set. They should be: 1 up and 2 down (9600 bps and PostScript).

Macintosh II: Upgrade for Apple SuperDrive

Can a Macintosh II be upgraded to support an Apple SuperDrive (formerly Apple FDHD)?

This article has been archived and is no longer updated by Apple.
As noted in both "Technical Procedures for the Macintosh II" and in the Finished Goods price list, there is an upgrade for the Macintosh II to utilize the SuperDrive.

Published Date: Feb 18, 2012

Macintosh: When It Won‘t Let You Throw Files Away

I have a Macintosh Plus running System 6.0.3 and an Apple 20MB hard drive. I want to eliminate old data and old programs, but the system won't let me throw away any programs, data, or folders. The files are not locked, and the hard drive is very slow.

This article has been archived and is no longer updated by Apple.
There are a couple of things we would try.

First, rebuild the hard disk's desktop file by holding down the Command and Option keys while you start up the system. Hold both keys down until the dialog box appears asking you to confirm the desktop rebuild.

If that does not help, boot from a locked System Tools diskette and try to throw away the files, folders, and the System folder. Then, reinstall the System using the Installer. Another solution might be holding the option key down while throwing something into the trash

Once you have a re-installed the System file, do a file-by-file backup of the drive, re-initializing the drive, and then restoring the data and applications.

TA46232_Macintosh_Plus_ROMs_and_SIMM_Compatibility_(TIL07563).pdf

Macintosh Plus ROMs and SIMM Compatibility

Is it true that Macintosh Plus ROMs won't work with some third-party SIMMs? I bought some 1MB NEC SIMMs and get consistent "sad Macs" when I try to start the Macintosh Plus with them installed.

This article has been archived and is no longer updated by Apple.
We don't know of any reason to upgrade ROMs for SIMM compatibility, nor of any incompatibility with the mentioned SIMMs and the Macintosh Plus. If the Macintosh bombs only with those SIMMs installed, try them in another Macintosh model to see if it is related to the Plus or if one of the SIMMs is bad.

QuickDraw: Using It with an 8-bit Video Card

When and why should one use 32-bit QuickDraw? I assumed it was only for 24-bit color cards, but the Read Me in the Color folder in the 6.0.5 suite says it can also enhance 8-bit (256-color) situations.

I am using a Macintosh II with the original Macintosh Display Card 4*8, running 4 bits (16 colors), System 6.0.5, 5MB RAM, and Laser Driver/Prep 6.0.1. Would 32-bit QuickDraw help? (I presume if you use 32-bit QuickDraw, you should also use a 6.0.x-series Laser Driver/Prep.)

Do applications have to be specially written to take advantage of 32-bit QuickDraw?

Finally, with regard to the 6.0.x series Laser drivers, is there any safe, easy way to make black and white the default choice?

This article has been archived and is no longer updated by Apple.
In a Macintosh with an 8-bit video card, the only benefit is some dithering changes on 8-bit images. The use of 32-bit QuickDraw doesn't demand 6.0.x Laser drivers. The installation of 32-bit would probably not greatly improve your configuration.

Applications must be "32-bit clean" to take advantage of the capabilities of the newest 24- and 32-bit color boards. You will see applications begin to advertise that they are clean as more boards become available.

There is a modified version of the 6.0.x drivers called 6.0.1z that defaults to black and white. You might try it. For more information on 32-bit QuickDraw, see the article in the Tech Info library, titled "32-Bit QuickDraw Information".

SCSI Hard Disks: Mounting Without Restarting

I want to mount Apple SCSI hard disks without restarting the system. Is there any way to do this from the System software or any of the included utilities? If not, can you suggest any other utilities that would enable mounting Apple SCSI drives without restarting?

This article has been archived and is no longer updated by Apple.

Yes, there are several shareware utilities that allow mounting of SCSI volumes without a restart. They are: SCSI Probe by Robert Polic, SCSI Info by Bob Easterday, and SCSI Tool by Paul Mercer. SCSI Probe is available online.

FileMaker II: Network Problems

I am supporting an 11-node AppleShare network (2 Macintosh SEs and 9 Macintosh Plus computers). The software versions are:

* AppleShare II 2.0.1
* Finder 6.1
* System 6.0.3
* FileMaker II 1.1v2

Cabling for this network is PhoneNet wired in a passive star. Total cabling distance is less than 400 feet. All 11 workstations can log in to the file server, print, and use the InBox E-mail system. All workstations have 2.5MB of RAM.

My problem is that although nine workstations can share the same file from FileMaker II concurrently, the other two workstations are denied access to the shared FileMaker II database.

The two "denied" computers share a common cable with one other Macintosh. However, they are at the end of the leg. These are Macintosh Plus computers. I cannot get these machines to share the same database, even if they are the only machines trying to log in. What's the problem?

This article has been archived and is no longer updated by Apple.
You mention they are at the end of the leg of the star: have you tried moving one or both Plus systems to a different connector to see if that's the problem? If the problem continues at another physical location and you can log on to the server, we suggest that the problem lies with FileMaker rather than the Macintosh or the network.

Because you can access the server; and print, copy files, and so on; we assume that basic network integrity is good; and the problem lies with FileMaker itself. It appears that you are exceeding the maximum number of simultaneous users. We would suggest that you contact Claris for a solution, if our suggestions don't alter the performance of these two systems.

Apple IIGS Network: "Looking for AFP fileservers" Message

I have a problem concerning a Macintosh file server and Apple IIGS lab. I installed the AppleShare File Server software and Aristotle on a Macintosh SE. Ideal Learning installed their Podium software. The installation was successful and the lab operated for two months without a problem.

During the summer, the lab was moved to another room and reconnected. After a few days, problems developed. When the Apple IIGS computers were turned on, we got the normal routine (the dots going across the top of the screen), and then, when the message "Looking for AFP fileservers" came on, the IIGS screen showed what appeared to be hex characters, and it locked up. The IIGS had to be restarted.

The file server appeared to be working without problems. I then re-installed the AppleShare File server software, and the same thing happened. Next, I re-installed the Macintosh OS, updating to System 6.0.5. The same thing happened again. I reformatted the hard disk and restored from a backup. The system worked for about a week, when the same problems developed.

There are five other labs in the school system with the identical set-up, and they are all operating without any problems.

This article has been archived and is no longer updated by Apple.
We would check the server and make sure that GS/OS has been properly installed--with the Installer--and that all the necessary files are there. After you verify that, take a look at each Apple IIGS computer.

If the problems show up on all systems in this network, take one of them to another network and see if it starts properly there. Also, check to see what is happening before the network fails. Maybe a student is trashing some crucial files within the server folder or within the GS/OS system folder on the server.

Macintosh: Typesetting with TeleTypesetting‘s MicroSetter

This article has been archived and is no longer updated by Apple.

MicroSetter, from the TeleTypesetting Company, converts Macintosh documents into a form acceptable to Varityper typesetting machines. The product includes the MicroSetter desk accessory, cables, conversion software, and connectivity software.

MicroSetter can connect to both digital and non-digital Varitypers. In the case of digital Varitypers, a "ruling" option lets the user typeset rules, boxes, and graphics from MacPaint-type applications.

MicroSetter can handle documents created by Ready,Set,Go, Page Maker, Microsoft Word, MacWrite, and MacDraw. (Graphics from Quark XPress and Cricket Draw are not compatible with MicroSetter.)

The MicroSetter desk accessory is used in two ways:
- to convert a document to Varityper format,
- then to send the document to the Varityper.

The Varityper can't generate all the text and graphics that the Macintosh can. A non-digital Varityper can do text only. And a digital Varityper can't do screen fill patterns, rotated type, circles, or arcs (but with the "ruling" option can handle text, bit-mapped graphics, lines, and boxes).

Published Date: Feb 18, 2012

Macintosh: Correcting Garbled System Numerals

All the numbers in my Control Panel, on SuperClock, in the Get Info box, in About the Finder, or any other system-related window are messed up. For example, in About the Finder (About This Macintosh in System 7), you might see "Largest unused Block: 1,?22K" instead of "Largest unused Block: 1,722K", or "Total Memory: 3,89>K" instead of "Total Memory: 3,898K" My SuperClock says "6:2 PM" instead of "6:20PM."

Occasionally, a number is represented by a character. However, when I type numbers into applications like Word or Excel, the numbers are always represented correctly.
This article has been archived and is no longer updated by Apple.
There are two possible solutions worth trying. First, try resetting the parameter RAM (PRAM). PRAM could be causing some of the numbers to be misrepresented. (Search for "PRAM" in this database for how to reset PRAM. The procedure is different for System 7.x than for System 6.x.)

If the problem persists, throw away the System Folder in use and reinstall from known-good, locked, original System diskettes.

Finally, if none of these works, have the logic board checked. It may need to be replaced.

TA46239_Apple_II_Function_of_Start__(TIL07573).pdf

Apple II: Function of Start 13

I have an Apple IIc Plus with a 5.25-inch drive. Do I need a file called Start 13 on my system for the drive to work properly?

This article has been archived and is no longer updated by Apple.
The file Start 13 was used early on when the Apple II went to a 16-sector disk format. Start 13 made it possible for older, 13-sector diskettes to be read. You don't need it for the Apple IIc to work with current diskettes.

Published Date: Feb 18, 2012

Macintosh SE: System Software 6.0.5 vs 6.0.2

I have 50 Macintosh SEs on an AppleShare network. The SEs shipped with System 6.0.5 software. As far as I can tell, this version of the system software does nothing for the SEs and only consumes more memory than System 6.0.2. Could I install 6.0.2 on them instead?

This article has been archived and is no longer updated by Apple.
You are basically correct; there is little advantage for those machines to run System 6.0.5. If you wish to use 6.0.2, go ahead.

Published Date: Feb 18, 2012

Macintosh: SLIP, TCP, and PPP

I use DAL and want to connect remotely from a Macintosh IIfx to a Sun workstation. I also want to have terminal emulation and file transfer. Do you know of a TCP/SLIP product that does this?

This article has been archived and is no longer updated by Apple.
SLIP is an asynchronous serial line protocol developed for running TCP/IP over serial communications lines in a point-to-point configuration. SLIP was developed to transmit IP packets over low-speed, sometimes noisy, asynchronous communications lines where error recovery and an efficient line protocol is needed. A new, serial, line protocol named "PPP" is replacing SLIP. PPP uses an even more efficient means of establishing a point-to-point IP connection.

MacTCP 1.0.2 has hooks for different third-party link-layer modules. This helps the development of interfaces to SLIP, PPP, and any other link layer, like broadband, X.25, FDDI, and so on. Apple does not provide support in MacTCP for SLIP or any other serial line protocol. These have to come from third-party developers.

Published Date: Feb 18, 2012

LaserWriter IINTX: ROM Upgrade and Font Rendering

Does the new version of PostScript on version 3.0 of the ROMs on the LaserWriter IINTX speed up Font rendering as does the new PostScript in the Personal LaserWriter IINT?

This article has been archived and is no longer updated by Apple.

The new version of PostScript for the LaserWriter IINTX does not improve font rendering in most operational modes. The major differences between the 3.0 and older ROMs are:

* Software switching from LaserJet emulation to PostScript
* Font cleanup in LaserJet emulation
* Better disk management routines
* PostScript 51.8.

Published Date: Feb 18, 2012

LaserWriter IINT: No Plans for a ROM Upgrade

Is Apple going to give the LaserWriter IINT new ROMs, so that users can have PostScript 51.8 like in the LaserWriter IINTX? Also, does the new LaserWriter IINTX ROM upgrade work in a LaserWriter IINT?

This article has been archived and is no longer updated by Apple.
No, there is no upgrade planned for the LaserWriter IINT ROMs, nor will the LaserWriter IINTX ROMs work in the LaserWriter IINT.

Published Date: Feb 18, 2012

Hard Disk 20SC: Can‘t Be Startup Device for Unenhanced Apple IIe

The Hard Disk 20SC connected to my Apple IIe is not booting. However, when I boot ProDOS 1.1.1 from the floppy drive, the system recognizes the data on the Hard Disk 20SC. The ProDOS disk shows the "slot configuration" as slot 7 being used. The drive shows that the BASIC.SYSTEM and PRODOS files are there. Is there supposed to be another file?

This article has been archived and is no longer updated by Apple.
In general, a bootable ProDOS volume needs only the PRODOS and BASIC.SYSTEM files. You can substitute a different file for BASIC.SYSTEM as long as the substitute's name ends with .SYSTEM and has a filetype of SYS. If you have only these two files, you boot to BASIC.

The most likely cause is that your Apple IIe is unenhanced. Only the enhanced Apple IIe recognizes the SCSI interface card during startup. An unenhanced Apple IIe can't start up from the device, but you can use it after starting up from some other device.

If this is the problem, get an Apple IIe Enhancement Kit (Finished Goods part number A2M2052, SRP).

Macintosh System 7.01: Compatible with Plus and Later

We want to standardize systems from the Macintosh Plus computers on up. Does version 7.0.1 work okay on all models?

This article has been archived and is no longer updated by Apple.

Yes. System 7.0.1 is good for any Macintosh from the Macintosh Plus on up. You should have no problems upgrading existing installations to this version. Apple also recommends that you install the System 7 TuneUp 1.1.1.

Published Date: Feb 18, 2012

Macintosh Display Card 824 GC: HyperCard 1.2.5 Compatibility

I just got a new Macintosh Display Card 8*24 GC for my Macintosh IIfx (running System 6.0.5). I am running into a problem when trying to run HyperCard 1.2.5. If the accelerator is disabled, everything is fine. However, with the accelerator on, the outlined hand in HyperCard turns black and the system does not react when I press buttons. Only browsing is affected. When a button tool (or other tool) is selected, it seems to work okay.

I need to use a custom HyperCard 1.2.5 stack off and on during the day. Right now, I must restart the computer to disable the card to use HyperCard.

This article has been archived and is no longer updated by Apple.
An unadorned HyperCard 1.2.5 stack should work fine. Your stack may have an XCMD or XFCN that is interfering with the altered QuickDraw command set that the Macintosh Display Card 8*24 GC uses. As externals are processed by HyperCard when a stack opens, any incompatibility (not bugs, though) shows up.

We recommend that users of the Macintosh Display Card 8*24 GC upgrade to HyperCard 2.0, mainly for the sake of performance. HyperCard 2.0 uses true QuickDraw commands, which the Display Card 8*24 GC accelerates. (Earlier versions of HyperCard bypassed QuickDraw entirely.) Older stacks should work, but performance will not improve.

Published Date: Feb 18, 2012

A/UX: Macintosh IIfx Requires A/UX 2.0 or Later

Article Change History

08/31/92 - REVIEWED
o For technical accuracy.

I bought an Apple HD 80SC drive with A/UX 1.1 installed. When I connected the drive to a Macintosh IIfx (with the special IIfx terminator), I couldn't launch A/UX. However, other folders on the drive open fine. With A/UX, I get error messages:

SCSI RESET
DISC C1D0S0:SCSI TIMEOUT
GENERIC DISC C1D0S0 FATAL ERROR:LOGICAL BLOCK 0,
PHYSICAL BLOCK 1869875042
CHROOT FAILED
SASH#

This article has been archived and is no longer updated by Apple.
To run A/UX on the Macintosh IIfx, you must have A/UX 2.0 or any later version. Version 1.1 gave you this particular error message, because it doesn't know how to use the IIfx DMA SCSI scheme. If you want to use A/UX on a IIfx, you must upgrade.

PrintServer: Length Limit on Device/Zone Names

My Macintosh II is in a zone (Advertising/Professional Computers Zone) that is separated from the rest of our network by a bridge. The PrintServer captures the printer with no problems. I can see the PrintServer listed in the Chooser, and I can select the PrintServer, but when I try to print, it says "LaserWriter ÃPrintServer╚ could not be found..."

This article has been archived and is no longer updated by Apple.
Your zone name may be your problem.

The Chooser supports a maximum of 31 characters for a device or zone name, and your name is 34 characters. When the additional device names are appended to the data packet to make a complete address string, the string gets truncated by a lower-level AppleTalk routine. At that point, the name string doesn't match the actual address, and a search for that device fails.

Shorten the zone name to something under 30 characters. Also check device names to verify that they, too, are under 30 characters.

Apple IIGS: Disk Drive Slot Assignments

This article has been archived and is no longer updated by Apple.

Depending on the operating system and the available combination of drives, the Apple IIGS can use disk drives in a number of different slot assignments. Below are some guidelines for determining the slot assignments.

Under DOS, ProDOS 1.1.1, ProDOS 1.2 (ProDOS 8), and ProDOS 16, you may use the slot number to refer to hard drives and floppy drives using an interface card. Disks may also be called by ProDOS pathnames without regard to slot locations.

The Apple IIGS SmartPort, controlled by the firmware in the IIGS, includes the internal RAM disk and ROM disk as well as any external drives connected to the SmartPort. These drives are referenced in slot 5 because the IIGS takes SmartPort to be slot 5. There are exceptions in the use of the SmartPort: it's not available under DOS or ProDOS 1.1.1.

ProDOS 1.2 (ProDOS 8) permits up to four devices connected to the SmartPort. If four drives are found on the SmartPort, the first two drives are considered to be in slot 5 (drives 1 and 2), and the last two drives are "found" in slot 2 (drives 1 and 2). If the RAM disk is active, it occupies slot 5, drive 2, and remaining drives are moved down in the sequence to slot 2, drive 1 and slot 2, drive 2, if necessary.

ProDOS 16 allows the SmartPort up to six devices, all found in slot 5; if activated (from the Control Panel), the RAM disk occupies slot 5, drive 2. If both RAM and ROM disks are both activated, the ROM disk will be found immediately after the RAM disk. If RAM and ROM disks are available and if only the ROM disk is activated (from the Control Panel), the ROM disk will be found in drive 2.

TA46252_Personal_LaserWriter_NT_Using_with_Amiga__(TIL07590).pdf

Personal LaserWriter NT: Using with Amiga 2500

Are there drivers for the Amiga 2500 that let it communicate with the Personal LaserWriter NT via the computer's RS-232 port?

This article has been archived and is no longer updated by Apple.
As of October 1990, our databases show nothing about printing PostScript from an Amiga. Depending on your application software (or interfacing drivers), you have two choices:

* Connect serially to the LaserWriter and use its built-in PostScript.

* Set the LaserWriter to Diablo 630 emulation and print to it as if the LaserWriter were a "dumb" printer.

The Diablo 630 mode is a no-frills, daisy-wheel emulation, so if you have an application that doesn't mind if you strip out control codes, you'll be in business. The LaserWriter Owner's Guide has much more on this type of connection and interface capabilities.

TA46253_AppleCD_SC_Fan_Deleted_in__(TIL07591).pdf

AppleCD SC: Fan Deleted in 1990

The outside of the box of my new AppleCD SC says: APPLE CD ROM/NO FAN. When did Apple stop including the fan? Why?

This article has been archived and is no longer updated by Apple.
Apple stopped including the fan in the AppleCD SC in early 1990. We had found that the fan was drawing an excess amount of dust and other airborne particles into the CD mechanism and depositing them on the optical read head. The fan turned out to be unnecessary, so it was removed completely.

AppleShare 2.0: Partitioning, Zones, and Restricted Log-In

I would like to restrict the total available space of a zone to that preset by a partition. Does AppleShare 2.0 let the hardware partitioning of the server hard drive correspond to the zones of the network?

Also, could I have multiple hard drives and assign each to a particular zone? Can LaserWriters be assigned and restricted to a zone?

This article has been archived and is no longer updated by Apple.
AppleShare File Server recognizes hard-drive partitions, depending on how well-written the partitioning software is. There are probably some partitioning utilities that are not compatible with AppleShare. Contact the utility's vendor to make sure it works.

In the larger picture, you can't specify login privileges based on zone, but you can do the same thing by setting the privileges based on user ID. The login list is specified by volume, so you can give each volume a list of "good" users and by telling it to disallow "guest" log-ins. This will, in effect, do what you need.

AppleShare Print Spooler: No Demand-Based Routing

I have an Apple IIGS lab that is configured with several teacher accounts, but without individual student accounts. During a particular session all the students log on with the same username, and are therefore attached to the same printer. Can the AppleShare print spooler be configured to capture input from all the GS computers and spool it to two or more ImageWriters?

This article has been archived and is no longer updated by Apple.
As of October, 1990, there was no spooler that could intelligently divert output to different printers, based on the number of jobs in each queue for each printer (nor even simply divide all output in half and send each half to a different printer). Our databases don't show a product that can do this, nor can the AppleShare Print Server do it. All of the products listed have a one-to-one spooling capability, and the user has to change the spooled device manually.

Depending on your software and user configuration, you may want to try splitting the users into two groups. Instead of having everyone log on with the same username, make two usernames and have each print to a different printer. You can put each username into a single group and set the access privileges at the group level to keep everything the same.

AppleShare: Troubleshooting PrintShare Problems

We have set up an AppleShare network with PrintShare running. We have had frequent system bombs on the server. Although we made some changes, and things seem to go well for a while, system bombs recur.

In addition, we get lots of error sheets from PrintShare. Many of them have to do with "stack underflow". This situation occurs frequently on another AppleShare network, but without the crashes.

Our server is a Macintosh SE/30 with 4MB of RAM and an external 80MB hard disk running System 6.0.5, AppleShare 2.0.1, and PrintShare 2.0. We partitioned the disks with SilverLining Software (for a password-protected partition).

Our network includes three volumes on the server. The network contains about 15 workstations, three older LaserWriters (captured by the PrintServer), and three ImageWriters.

All workstations are Macintosh Plus computers. They run System 6.0.5, Laser drivers v. 5.0, the Virex INIT for virus checks, and no unusual INITs, DAs, or cDEVs.

This article has been archived and is no longer updated by Apple.
Three things come to mind. First, make sure that the LaserWriter driver used by everyone (including the server itself) is at least version 5.2. Versions 5.0 and 5.1 have some known bugs which could contribute to the problems.

Second, make sure that NO extra INITs or cDEVs are running on the server. Given the way AppleShare works, these extra INITs can cause a performance decrease and occasional system bombs. AppleShare is too time-sensitive to tolerate much interruption.

Third, everything could come down to a defective SCSI driver written to the hard drive. Make sure that you use the very latest version of SilverLining and reformat the drive. Make sure that backups are file-by-file rather than partition-by-partition, as any slight mistake in partition size may cause lots of problems during the restore operation. After formatting, re-install the File and Print Servers from diskette, rather than from the backup.

Chooser: How Device Lists Are Sorted

What determines the order that items appear in the Chooser's scrolling fields?

This article has been archived and is no longer updated by Apple.

The Chooser broadcasts a signal to the entire network (or zone, if applicable) requesting that all devices of DEVICETYPE respond with their network information. The order in which those devices respond determines their order in the selection list. (A lightly-loaded network almost always returns the devices in the same order, because the devices aren't too busy to respond to the Chooser immediately.)

The order in which zone names are listed depends on the router you're using. Because this information is usual not dynamically compiled, most routers sort the list alphabetically for readability.

Apple IIc Plus: Mouse Paint

Is it possible to copy the Mouse Paint drawing program from a 5.25-inch disk (p/n 680-3005-B) onto a 3.5-inch disk for the Apple IIc Plus. If so, what is the procedure?

This article has been archived and is no longer updated by Apple.

It is possible. First, copy file-by-file everything from the 5.25-inch disk to the 3.5-inch disk. Then, make sure that the name of 3.5-inch disk matches the original 5.25-inch disk.

The program expects to find itself only on disks with that particular name, and it assumes that its files are in exact places. If you don't change the name or move the files, you'll be fine.

You can use the Apple System Utilities diskette, which should come with every Apple 3.5 and 5.25 Drive accessory kit to copy the files. There are a variety of third-party disk utilities available that can also do this. Check the Redgate Buyer's Guide library on AppleLink for possible solutions.

DuoDisk Drive: How to Use It with Apple IIGS

I want to connect a DuoDisk Drive to an Apple IIGS. How is this done, and how will it affect my 3.5-inch drive and 5.25-inch drives?

This article has been archived and is no longer updated by Apple.
The DuoDisk usually acts like two Apple 5.25-inch drives. There are a couple of compatibility issues, however:

* If you plan to attach the DuoDisk to the SmartPort on the back of the Apple IIGS, and it is going to be the last device in the chain, then you need to make sure the DuoDisk's analog board has a particular modification. If it lacks this modification, you can do it yourself. Details can be found in both "Tech Procedures for the DuoDisk" and the Product Notices section of the "Apple Service Programs" binder.

* If you have a newer IIGS, with rev 03 ROMs and 1MB of RAM installed on the logic board, you CANNOT attach the DuoDisk to the SmartPort at all: you must use a DuoDisk interface card, just as if the IIGS were an Apple IIe instead. You can buy this through Service (part number 661-92131).

If you meet these two considerations, the DuoDisk will not affect your other attached disk drives.

Finder: "file could not be written and was skipped" Message

When copying a file from one disk to another, I got the message:

This file could not be written and was skipped

The original file seems to open and work fine.

This article has been archived and is no longer updated by Apple.
Here are two possible reasons for this:

This error indicates that your destination volume has a problem with it. If it is a floppy, reformat it. If it is a hard disk, run a good disk utility against it to discover the problem. Then take appropriate action.

The problem could also lie within the file or application. Examples such as a damaged or copy-protected file or application may also cause this message to occur. Make sure you are using a clean copy. You may want recopy from the original source to make the file is undamaged.

TA46266_Personal_LaserWriter_NT_MB_SIMMs_(TIL07604).pdf

Personal LaserWriter NT: 4MB SIMMs

Are the 4MB SIMMs for the Personal LaserWriter NT the same as those in the general market?

This article has been archived and is no longer updated by Apple.
The requirements for the 4MB SIMMs are the same as for standard Macintosh II SIMMs, but they must be rated at 100ns or faster. They must also fit in a significantly smaller space than is allowed by the Macintosh II family. This eliminates 4MB SIMMs made from lots of 1MB DRAM chips.

A number of vendors advertise compatible 4MB SIMMs. Just check the ads in your favorite Macintosh-oriented magazine, or check with an Authorized Apple Dealer.

Macintosh IIcx: Mouse Failure and Memory

Article Reviewed Only: 10 July 1992

I have a Macintosh IIcx with memory expanded to 8MB (four 80ns and four 120ns chips). When I put the 120ns in bank A and the 80ns in bank B, I got an error chime on startup. I swapped the two banks and was able to use the system. Now, I am finding that when I do memory-intensive operations, my mouse freezes. My debugger points to the memory as the problem.

Is my configuration correct--four 80ns 1MB SIMMs in bank A and four 120ns 1MB SIMMs in bank B? Does the speed of the SIMMs determine which bank they go into? Might I have a flawed SIMM? Is the mouse freezing a symptom of reaching the memory limit (that 8MB may still not be enough for my purposes)?

This article has been archived and is no longer updated by Apple.
You wouldn't normally experience a problem using these SIMMs in the IIcx. All of them are at least as fast as the specifications require, and you're not mixing them within a bank (which, technically, is supposed to work, but often does not).

It sounds more like you have a defective SIMM, probably one of the 120ns. The self-test does not check the RAM as extensively as our diagnostics check it. It will try to make sure the lower addresses are good, which are the SIMMs in bank A, so the operating system will work correctly. Because it erred with the 120ns SIMMs in bank A, I would suspect those SIMMs first.

Mouse-freezing can be caused by a variety of things. Basically, mouse movement is controlled by the operating system, completely aside from all other system events. All mouse movements are posted to an event queue, as are almost all other events, and then the events are processed in order of their occurrence. If a mouse freezes, then the event queue is not being processed. This means the operating system is hung within an event, because the operating system is either within an event or getting the next event.

One such event that causes the system to hang is faulty RAM refreshing or memory I/O, but the most common is disk I/O. In this case, however, we think you're dealing with a RAM problem.

80-Column Text Cards: Apple II & II Plus Compatibility (11/96)

Does the Extended 80-column card work in the Apple II or Apple II Plus? If not, is there any way to upgrade an Apple II or Apple II Plus to 80-Column?

This article has been archived and is no longer updated by Apple.

The 80-Column Card and Extended 80-Column Card work only in the Apple IIe; they cannot be used in any other computer.

Our databases do not show an 80-column interface for the Apple II or Apple II Plus. There were once several on the market, but the demand for this type of card has almost disappeared. You might still be able to find these 80-column cards through some of the computer remarketing companies, or where use computer equipment is sold.

An alternative is to purchase an Apple IIe or Apple IIGS computer. You need to to contact computer remarketing companies, or look where use computer equipment is sold.

Macintosh: Internal Hard Drives Not Always Interchangeable

I have a Macintosh IIci with an 80MB drive. I also have a Macintosh IIsi with a 40MB drive. I want the 80MB in the IIsi and the 40MB in the IIci. Can I swap these drives? How about swapping drives between a Macintosh SE and a Macintosh IIsi?

This article has been archived and is no longer updated by Apple.
No. In one direction (IIci to IIsi), the hard drive is too large. In the other direction (IIsi to IIci), there's no way to mount the hard drive in the box. Your best bet is to get an external drive for the Macintosh IIsi.

There are also physical size and mounting bracket problems with swapping drives between a Macintosh SE and a Macintosh IIsi.

Published Date: Feb 18, 2012

TA46272_Apple_IIe_Memory_and_the_Power_Supply_(TIL07612).pdf

Apple IIe: Memory and the Power Supply

I was about to install additional memory in my Apple IIe when a friend told me that any memory over 128K would cause my transformer to burn out prematurely. He advised me replace it with a more durable model. Is there any truth to this?

This article has been archived and is no longer updated by Apple.
Memory, by itself, is not going to cause the Apple IIe power supply a problem. You should be able to install as many memory boards as the computer supports.

Some third-party power-supply manufacturers say that a fully-loaded Apple IIe (one with every interface slot filled) draws too much power and that you should install a higher-capacity power supply. However, we have not found that to be the case. Instances of supposed excessive power drain can usually be attributed to a damaged logic board, power supply, or interface card. A fully functional unit should not need a power supply upgrade.

TA46273_Apple_IIGS_and_Integer_BASIC_(TIL07614).pdf

Apple IIGS and Integer BASIC

I am trying to run old Apple II programs written in Integer BASIC on an Apple IIGS (original Woz version with 256K of RAM). I can list the programs with the CAT command, but can't run them.

This article has been archived and is no longer updated by Apple.
The Apple IIGS can run Integer BASIC programs, but only under DOS 3.3, not under ProDOS. ProDOS is not compatible with Integer BASIC (though it is compatible with Applesoft BASIC).

To run your programs, first start up from a known-good DOS 3.3 System Master (or other DOS 3.3 startup disk that loads Integer BASIC in RAM).

Published Date: Feb 18, 2012

ImageWriter II: How to Set Line Length from an Apple IIGS

Is there a way, when writing a BASIC program on the Apple IIGS, to send a command string to an ImageWriter II printer (like Control-i 40N) to limit the number of characters that the ImageWriter prints on a line?

This article has been archived and is no longer updated by Apple.
You cannot set that limit within the ImageWriter, but you can set it within the IIGS's serial port firmware. In fact, it's the command you cited above. The ImageWriter prints until it physically reaches the end of the platen. So, if you need a guaranteed way to force a premature carriage return, set the serial port's firmware.

Published Date: Feb 18, 2012

ImageWriter II: Worn Spring Affects Print Quality

I have seen numerous ImageWriter II printers with this problem: once or twice in a page (during test print) the printing gets very light for a word or two, and then goes back to normal. Sometimes ribbon quality is blamed, but other times a new ribbon changes nothing.

I had one on which I changed the wire and gears that drive the ribbon, and it still did it. Moving the carriage back and forth by hand and holding the ribbon-advance knob with light pressure shows that sometimes the knob stops spinning briefly, as if the wire were sliding on the pulley. However, everything looks physically okay.

This article has been archived and is no longer updated by Apple.

The most common cause for the ribbon to stop spinning intermittently is a worn spring: the spring that maintains constant tension on the nylon wire that drives the ribbon-drive gear assembly. If the spring is worn, the constantly-varying tension within the ribbon cartridge (transmitted to the gear assembly), causes the nylon wire to slip.

Try replacing either the Ribbon Wire/Spring assembly (service part number 935-0001) or the spring only (available as a part of the Miscellaneous Hardware Kit, part number 076-0317).

LaserWriter and IBM PS/2: False "out of paper" Message

I have tried connecting an IBM PS/2 to a LaserWriter IINT. After following the directions in the manual (with the corrected "8" instead of "7") I got an error message on the PS/2--"printer out of paper"--although there was some in the paper tray. Where is the problem?

This article has been archived and is no longer updated by Apple.
The MS-DOS COM drivers scan for a particular signal on the RS-232 port for the paper-out condition. Given that, you're probably experiencing some type of cable problem. Most likely, you're missing a jumper on the PS/2 side. Check the DSR or CTS pins.

Also, the LaserWriter IINTX revised manual has about 25 pages of comprehensive details on connecting LaserWriters to IBM-compatibles. Check that for further troubleshooting.

Macintosh IIci: Configuring for Speed with Display Card 824 GC

What is the fastest configuration for a Macintosh IIci using the Macintosh Display Card 8*24 GC and a RasterOps ColorBoard 264 with an Apple Portrait Display Monitor in 2-bit black and white and the Apple 13-inch RGB monitor in 24-bit color? I have the Portrait Display Monitor on the 8*24 GC and the RGB monitor on the RasterOps card. Should I be using the IIci's internal video circuitry?

This article has been archived and is no longer updated by Apple.
There are three considerations here:

* You always have better performance using a NuBus video card than using the IIci's built-in video.

* The Macintosh Display Card 8*24 GC speeds up all QuickDraw processing, as long as it's active and as long as the "other" video board lets it. Check with RasterOps to see what their card does.

* You get more for your money when you put the greater pixel-depth monitor on the faster card, probably the Macintosh Display Card 8*24 GC.

Published Date: Feb 18, 2012

LocalTalk PC Card: How To Free Memory To Print

We installed a LocalTalk PC card on a 386 AT clone with 1MB RAM. We use this PC to download stock quotations. The company uses Macintosh SE/30 and IIci systems for everything else. We want the 386 AT to print its stock data to the LaserWriter IINT.

When we try this, we get a message saying we don't have enough memory. We are running MS-DOS, LocalTalk PC software, and the program for the financial service. How can we print reports to the LaserWriter?
This article has been archived and is no longer updated by Apple.
There are several ways to minimize the RAM allocations in an MS-DOS machine, which may free up enough space to run all of the applications at once. You may try reducing the number of buffers allocated to DOS, for instance.

If you configure AppleShare PC for print services only, you can expect it to take up 62K to 90K of base RAM. Because AppleShare PC must reside in the 0K to 640K range, you may free enough RAM for everything, if you can configure other portions of the operating system to run in the 640K to 1MB range.

We advise you to minimize existing RAM allocations first and re-install AppleShare PC with the minimum services. Then, if that doesn't work, start moving applications into higher memory.

TA46282_Macintosh_IIsi_Upgrading_Memory_to_MB_(TIL07628).pdf

Macintosh IIsi: Upgrading Memory to 5MB

What Apple part number is needed to upgrade the Macintosh IIsi memory to 5MB or 10MB?

This article has been archived and is no longer updated by Apple.
The Macintosh IIsi can be upgraded to 5MB of RAM by using the same memory upgrade kit as used for the Macintosh IIci. Ask for Finished Goods part number M5952LL/A.

Published Date: Feb 18, 2012

AppleShare Network: Auto-Logon Problem

I have one and sometimes two Macintosh computers on my AppleShare network that have been giving me some problems. When these systems are turned on in the morning, they automatically ask for a password, so they can log on to the net. Some mornings, however, they come up and bypass the logon screen and start up without even going to the server.

To remedy this, I go to the Chooser, select AppleShare, and redefine what it is that I want saved for the next time the machine starts. Then, it works fine for quite a while. The network is okay, because there are machines before and after these machines on the net. I have rebuilt the system (6.0.3), re-installed AppleShare numerous times, and so on.

This article has been archived and is no longer updated by Apple.
Automatic logon to an AppleShare server is done through two pieces of software: The AppleShare file itself (the RDEV that appears in the Chooser and is also an INIT) and the AppleShare Prep file, which stores the auto-logon information (volume name, password, and so on).

If the machines fail to log on (but AppleShare is active) you can manually mount the volumes without rebooting--then the most likely problem is that the RDEV can't find the AppleShare Prep file during startup. This could be due to either corrupt System software or a corrupt directory structure. Because you've already rebuilt the System, it's probably the latter.

Run Disk First Aid against the hard drive. This does minor repairs on the directory. You may also want to rebuild the Desktop. A definite cure would be to back up and reformat the hard drives, but you will probably be able to solve your problem without resorting to this.

Macintosh: Using the Alarm Clock

This article has been archived and is no longer updated by Apple.

To see the clock, choose Alarm Clock from the Apple Menu. A single box displaying the time will appear on screen. Clicking on the flag to the right of the time will bring up two more boxes under the time display. The bottom box contains icons for the alarm, date, and time; the middle box contains the setting for the icon selected in the bottom box.

To set the alarm, date, or time:

1. Choose Alarm Clock from the Apple Menu.

2. Click on the flag to the right of the time display. The setting and icon boxes appear.

3. Click in the bottom box on the icon for the setting you want to change.

4. Click in the middle box. Scroll arrows appear.

5. Click in the middle box on the setting you want to change. To change the setting, click on the scroll arrows or type the new settting.

6. Set the clock by clicking on another icon or clicking on the Close box in the upper left corner of the time display.

When you select the alarm icon, an on/off switch icon shows up on the left of the alarm setting in the middle box. Small lines radiate from the alarm icon in the bottom box when the alarm is on. When the alarm goes off, the speaker beeps once and the Apple menu flashes.

When the Apple on the Menu bar is flashing, it means that the alarm has gone off. To turn off the alarm, choose the Alarm Clock from the Apple menu; if the clock is on screen, get to the clock's icon box and click on the date or time icon.

Macintosh: Setting the Serial Port Baud Rate

How do I set a device to a different baud rate on a Macintosh serial port?

This article has been archived and is no longer updated by Apple.

The ability to set the baud rate for the Macintosh serial port lies with the application and/or serial port driver you're using. In most instances, the baud rate is predetermined and cannot be changed. The most notable exception is modem communication, where you can set baud from within the application. There is no default (or built-in) method for setting baud.

We would suggest contacting the driver's publisher for this type of information, because it varies from driver to driver.

Apple MIDI Manager: Compatibility & Availability

Does Apple sell a software program called MIDI Manager?
This article has been archived and is no longer updated by Apple.
The Apple MIDI Manager is a developer's tool, not a stand-alone application or utility. It is available as part of the downloadable file MIDI Management 2.0.2 available from online services.

The following files are included in MIDI Management Tools 2.0.2:

- Apple MIDI Driver 2.0.2
- MIDI Manager 2.0.2
- PatchBay Help
- PatchBay 2.0.1
- PatchBay DA 2.0.1
- Serial Switch 1.1

The Apple MIDI Manager version 2.0.2 is compatible with System 7.5 but is not supported by Apple because it is considered a development tool.

Note: Neither QuickTime 2.0 or 2.1 have MIDI Manager built-in, but they do have MIDI capability.

TA46289_System_x_Disk_Distribution_(TIL07635).pdf

System 6.0.x: Disk Distribution

Are there sets of four 800K disks of System Software 6.0.7 for people without 1.4 MB SuperDrives?

This article has been archived and is no longer updated by Apple.

Yes. You can still obtain System 6.0.x on 800K disks through any authorized dealer. Macintosh System Software 6.0.8 is the latest version of System 6.0.x, and it is available on either 800K or 1.4 MB (high-density) floppy disks. Remember that the files on these disks are organized in a special manner. You cannot simply take the two high-density disks containing 6.0.8 and spread the files randomly to four 800K disks. This will not work. You must have the System Software version 6.0.8 disks that are intended for the 800K format. These are labeled "System Tools," "Printing Tools," "Utilities 1" and "Utilities 2."

Published Date: Feb 18, 2012

Macintosh: Network Fax Modems (9/93)

Is there a network fax modem for the Macintosh?

This article has been archived and is no longer updated by Apple.
There are three products that may serve your needs.
These include:

* Xecom's QuadPort Network Modem family
* Ricoh's DX-1
* Microsoft's FaxGate

QuadPort Network Modem Family from Xecom

These are four channel NuBus data and fax/data modem server products for the Macintosh II family.

The QuadPort Network server product line provides centralized, high-density, telecommunications resources inside a Macintosh II computer. Users can share as many as 24 modems or fax/data modems in AppleTalk, EtherTalk, or TokenTalk network environments.

DX-1 from Ricoh

Ricoh's DX-1 lets Macintosh and many laptop computers communicate with local and remote Group 3 fax machines. Under it, a local fax machine can serve as a computer printer and scanner.

When DX-1 software runs from a computer on a network, users can transmit faxes from computer to computer on the network, without the use of fax boards or fax modems. It can serve as a fax traffic director at a hub unit, automatically saving received documents to disk or switching them to a local fax for printing or storage in fax memory.

FaxGate from Microsoft

With FaxGate and BackFax, a single fax modem and phone line can serve the fax needs of all users on a Microsoft Mail or QuickMail network. Memos prepared with either LAN-based mail system can be routed to recipients at fax machines around the world in addition to, or instead of, recipients on the local network.

Note: BackFax software is no longer available. Fax Pro for Macintosh from Delrina Technologies replaces BackFax.

To locate a vendor's address and phone numbers, use the vendor name as a search string.

Article Change History:
19 June 1992 - Reviewed for technical accuracy.
21 October 1992 Revised to say that FaxGate software is supported by Microsoft, not Solutions, Inc.
2 September 1993 - Added note that BackFax isn't available.

Published Date: Feb 18, 2012

Macintosh: How to Access Novell Servers

Can I use a Macintosh as a server within our Novell system? Would it permit mail both within the Novell and external to other AppleTalk nodes? Would MS-DOS computers encounter problems sending or receiving this type of mail? Would I need any special changes or hardware, other than a Macintosh as a server?

This article has been archived and is no longer updated by Apple.

You can do this type of configuration, but with a different server: you need a Novell server with the Macintosh computers getting access from it (as opposed to a Macintosh server).

Novell sells a connectivity solution called "NetWare for the Mac" that lets a Macintosh access a Novell server in much the same way as Macintosh computers access an AppleShare server. There are some limitations, such as requiring Ethernet cabling at the server end, but it is a good solution.

For further information, search the Tech Info Library under "NetWare" and "Macintosh" to get the relevant articles. There is a three-part article that fully explains the configurations, along with related material.

TA46293_Access_II_Printing_Files_(TIL00764).pdf

Access II: Printing Files

This article has been archived and is no longer updated by Apple.

Access II cannot send files directly to a printer. You may, however, (1) record the file to disk and then print it off-line, or (2) print the recording file without going off-line by choosing 'Print a file' from the Utilities menu of Access II.

Published Date: Feb 18, 2012

Macintosh Portable and LCD Overhead Projection

What LCD overhead projectors are available for the Macintosh Portable?

This article has been archived and is no longer updated by Apple.
You may want to consider Sayett Technology's Datashow HR/MP high-resolution LCD system. You can project graphic screen images from a Macintosh Portable, Plus, or SE. The display contrast of 20:1 puts out bright, clear, projected images with a display resolution of 512x342 pixels for the Macintosh Plus, SE, and SE/30; and 640x400 for the Macintosh Portable.

To locate a vendor's address and phone numbers, use the vendor name as a search string.

Published Date: Feb 18, 2012

ImageWriter II: Bent Carrier Shaft Problem

The carrier-shaft bushing on the left and right of the printhead assembly were broken on our ImageWriter II; we replaced both items. Now, the left side is too snug when the right side is adjusted properly, and the right side has too much of a gap when the left side is adjusted properly.

This article has been archived and is no longer updated by Apple.

Other than playing around with more shim kits, you probably are looking at a bent carrier shaft. If the shaft is straight, then you should be able to adjust the printer with the shim kits; all but the very worst gap problems can be solved this way.

Published Date: Feb 18, 2012

AppleShare PC: Incompatible with Windows 3.0

I am using Microsoft Word under Windows 3.0. When I try to print to the AppleShare Print Server, I get the error:

Undefined; Offending Command:PS-Adobe_2.0

and the print job cancels.

This article has been archived and is no longer updated by Apple.
AppleShare PC and Windows 3.0 are incompatible and, unfortunately, there is no known workaround. You may be able to intermittently gain access to either print or file services with this configuration, but it is not stable.

On a side note, Farallon has since taken over the LocalTalk PC Card from Apple and has introduced new software for the card that is compatible with more PC programs than ever before. This may be a solution. Search under "Farallon" for the phone number and address of this third party company.

Published Date: Feb 18, 2012

AppleShare Print Server: Storing Outline Fonts

I have a Macintosh II and a Macintosh IIcx. From them, I print to a Linotype RIP30 and a LaserWriter IINTX. I put numerous outline fonts in the System folder of each Macintosh to give each full-font capability.

Is there a way to store all of the outline fonts at the server, instead of on each Macintosh? If there isn't, could I attach a hard drive to the LaserWriter II? Could I also attach a hard drive to the RIP30?

This article has been archived and is no longer updated by Apple.
Although it seems reasonable at first glance, you cannot install fonts on the Print Server for everyone to use.

The Print Server acts more like a "dumb" printer than anything else. That is, it looks like an Apple printer with LocalTalk functions only. It knows nothing of any special capabilities the printer may have, beyond what the LaserWriter or ImageWriter drivers tell it. Because of this, the Print Server doesn't have the ability to store any PostScript fonts.

You can install a hard drive on the LaserWriter IINTX to get the same effect. As for the Linotype printer, see your Linotype-Hell representative.

Article Change History:
23 July 1993 - Company title updated from Linotype to Linotype-Hell.
Published Date: Feb 18, 2012

PrintMonitor: "found an internal problem" Error

When I try to print from any of several applications the PrintMonitor becomes active and returns the following error message

PrintMonitor found an internal problem Where=-6; Why=-37

Without the PrintMonitor running, the system prints fine. LaserWriter and Laser Prep are installed from 6.0.5 with AppleShare V2.01.

This article has been archived and is no longer updated by Apple.
That type of error suggests that PrintMonitor has found an incorrect filename (or variable name) during execution. There are several things that could cause it. Here are some things to try:

* Start the system. Throw away the Spool Folder that's in the System Folder. Restart the system, and rebuild the Desktop (hold down the Option and Command keys all the way through the startup process, and OK the dialog box that appears).

* Recopy ONLY the PrintMonitor application from the Printing Tools diskette.

* After backing up your installed fonts and desk accessories, trash the System file from the hard drive, and run the Installer to put a new operating system on the machine. It's important that the System be trashed. The Installer will not necessarily remove a corrupted resource, so you may have the same problems after installing.

Published Date: Feb 18, 2012

System 6.0.5: Can‘t print in MultiFinder

My Macintosh IIcx prints in Finder to a LaserWriter IINTX, but doesn't print in MultiFinder. Instead, I get the dialog message

a printmonitor error has occurred

I have checked cabling, reformatted the hard drive, and reinstalled System 6.0.5 (thinking I might have a virus problem). Nothing worked.

This article has been archived and is no longer updated by Apple.
Because everything seems to work fine in the Finder, the hardware and most of the software is probably good. There are two more System resources that are pulled in when printing in the background under MultiFinder: Backgrounder and PrintMonitor. You may be experiencing a version incompatibility between these files. This is likely if you've recently upgraded your operating system.

We suggest replacing both of these files from a known-good 6.0.5 Printing Tools diskette. You can drag-copy them, but make sure you've booted your hard drive in Finder-only first. If you have a Spool folder in your System folder, throw that away too.

If that fails, try trashing and reinstalling the complete operating system using the Installer.

Published Date: Feb 18, 2012

PrintMonitor: Manual Feed and Flashing

I recently installed System 6.0.5 and Finder 6.1.5. Now, when I print on my LaserWriter IINTX, the PrintMonitor flashes. I have to select it and then click OK to proceed. With System 6.0.3, selecting Print did the whole thing without my having to select PrintMonitor.

This article has been archived and is no longer updated by Apple.
It sounds as if you have Manual Feed selected. Try again with Automatic Feed selected instead. If you have any doubts about the system upgrade, rerun the Installer to re-create the system files.

Published Date: Feb 18, 2012

Macintosh: How To Change "Number Of Copies" Default

Here's how to change the Print Manager's "Number of Copies" value from its default of 1.
This article has been archived and is no longer updated by Apple.
Note: ResEdit is a resource editor available from APDA, the Apple Programmer's and Developer's Association.

1. Use ResEdit to open the LaserWriter or ImageWriter file in your System Folder.
2. Change the "Copies:" field in DITL resource -8191. Change the number from1 to whatever number you like.
3. Save the change when you quit ResEdit.

Published Date: Feb 18, 2012

Personal LaserWriter NT: Spurious Paper-Out Light

I'm having a problem with a Personal LaserWriter NT. At power-up, with nothing connected to the printer, all three LEDs come on briefly, then they go out, and the paper-out LED starts flashing.

The manual indicates this means the printer is waiting for manual-feed paper, but obviously it shouldn't be. The engine test prints a normal test sheet.

This article has been archived and is no longer updated by Apple.
It sounds like the I/O board needs replacing, especially if you can get a good engine self-test out of the printer. We recommend replacing the board for test purposes.

Published Date: Feb 18, 2012

LaserWriter IINTX: 3.0 ROM Upgrade

What is the availability of the 3.0 ROM Upgrade for the LaserWriter IINTX? If so, when will it be available, and what does it do for you when installed?

This article has been archived and is no longer updated by Apple.
Here's a rundown of the LaserWriter IINTX ROM 3.0 capabilities:

There is a new version of LaserWriter IINTX ROMs being rolled into production in late May 1991. These ROMs contain an updated version of PostScript. PostScript version 51.8 has the following enhancements:

* Full support of software switching between emulations and ports. You can switch into and out of an emulation mode via software.

* Improved support of multiple SCSI disks. You can connect as many as eight SCSI hard disks to the LaserWriter IINTX SCSI port. Up to 80 percent of the hard disk with the lowest SCSI ID is used for font caching, with the remainder of that disk and all of any other connected hard disks used for downloaded fonts. Each hard disk is now formatted as a separate volume. Thus, you can move a disk (other than the startup disk) between systems without having to reformat.

* Improved HP LaserJet+ emulation. Four characters have been added that were left out of the original implementation of HP LaserJet+ emulation.

* Improved default settings for HP LaserJet+ bit map printing. Previously, bitmaps in HP LaserJet+ mode were interpreted at 7-bit, thereby ignoring a significant bit. The new ROMs default to 8-bit serial communications.

These new ROMs are found in any LaserWriter IINTX with a part number ending in 6004/A. Apple's Finished Goods part number for the LaserWriter IINTX Upgrade Kit is M0445LL/A.

TA46305_Apple_IIGS_Compatible_LaserWriter_Printers_(TIL07652).pdf

Apple IIGS: Compatible LaserWriter Printers

Which LaserWriters work with the Apple IIGS?

This article has been archived and is no longer updated by Apple.
As of GS/OS 5.0.4, the Apple IIGS supports LaserWriters that are available via the network and based on PostScript.

The Apple IIGS doesn't support LaserWriters that use SCSI or serial connections and are based on QuickDraw.

Published Date: Feb 18, 2012

LaserWriter: How Pages-per-Minute Is Calculated

The LaserWriter IISC specs indicate a speed of eight pages per minute. I am getting only five pages in about 4.5 minutes. The text is all one font and one size. Font sizes in multiples of four are installed in the system as suggested in the manual.

This article has been archived and is no longer updated by Apple.
The specifications for all printers on the market are based on ideal conditions. In the case of Apple's laser printers, the assumption is that a page has already been downloaded and imaged by the I/O board. In other words, eight copies of a one-page document print in one minute, if you start the clock when the first page is picked out of the paper tray. An eight-page document prints slower, as each page must be downloaded and imaged before being put on paper.

Macintosh Display Card 8■24 GC: Acceleration Questions

1) Will the Macintosh Display Card 8*24 GC accelerate the internal video circuitry on the Macintosh IIci?

2) Will the Macintosh Display Card 8*24 GC accelerate the Macintosh II Portrait Display Video Card?

This article has been archived and is no longer updated by Apple.

1) Question: Will the Macintosh Display Card 8*24 GC accelerate the internal video circuitry on the Macintosh IIci?

Answer: No. The Macintosh Display Card 8*24 GC accelerates only NuBus video cards that use frame buffering for video images. This works even better if the other video card supports NuBus slave mode. The Macintosh IIci's video circuitry does not use NuBus, nor does it support frame buffering. It will not be accelerated, except possibly in some very complex, pixel-deep images. This would be due to the Display Card 8*24 GC's processor and modified 32-bit QuickDraw. It probably would go unnoticed.

2) Question: Will the Macintosh Display Card 8*24 GC accelerate the Macintosh II Portrait Display Video Card?

Answers: The Display Card 8*24 GC accelerates the Portrait Display Card, but the increased performance would be at the low end of the spectrum (5 versus 30 times increase). This is because the Portrait Display does not support the NuBus slave mode.

Macintosh: "Resource Map is Bad" Message

While starting up my Macintosh SE, I saw the message "Resource Map is Bad." What does this mean? (Startup continued without further problems.)

This article has been archived and is no longer updated by Apple.
The resource map is a template that interprets the resource forks in any file into something intelligent. The Macintosh OS generates ID bombs (between -192 and -199) if it finds a serious problem in the resource fork.

We suspect that the message was generated by another application or utility. If it happened only once, don't be alarmed. However, we suggest running a file verification utility against the hard drive and possibly backing it up (just in case).

Published Date: Feb 18, 2012

PostScript: Common Causes of Errors

I tried to send an ASCII PostScript file (originally created under an IBM-PC application) to the LaserWriter. I get a PostScript error when I try to print documents with tables and formulas. The error that appeared on the screen is:

%%[Error:undefined;Offending Command:F0]%%

I can print text-only files okay. What's the problem? What do you recommend for troubleshooting PostScript errors?
This article has been archived and is no longer updated by Apple.
PostScript errors are usually generated by one of three things: a corrupt document, a bad printer driver, or a slight incompatibility between the version of PostScript in the printer and what the application thinks is there. Because you can print text without a problem, we suspect the latter of the three, particularly if you're printing to the original LaserWriter. To verify this, you may want to try to print to a newer printer, like a LaserWriter IINT.

If you're interested in getting deeper into Postscript troubleshooting, get some of the reference manuals on the subject. Adobe has books on the subject, as do other publishers. For more information, search on "Adobe" AND "3rd".

Macintosh: Products for Making Slides

Are there products that produce a slide directly (internally) from a computer's screen image?

This article has been archived and is no longer updated by Apple.
There are several products available for the Macintosh that generate slides from screen images. Look into any of these:

* Still Light from American Liquid Light
* PhotoMetric SlideMaker from General Parametrics Corp.
* Bravo Computer Slide Maker (BCSM) from Polaroid Corp.
* SlideWriter from Agfa Compugraphic Division

For vendor contact information, search the Technical Info library under the company name.

Still Light from American Liquid Light

Still Light is a digital film recorder that captures images and generates boardroom-quality 35mm slides, negatives, transparencies, or instant prints.

Drawing on up to 16.5 million colors, Still Light accepts PICT or PICT II files from popular Macintosh applications. Because of its batch processing capability, it can produce up to 36 images, unattended, without having to load the software where the files were created.

Still Light's standard features include the Still Light video graphics card, software, adapter cables, film recorder, 35mm camera back with autowinder, instant film back for 3.25x4.25-inch print film, Polaroid Instant Film Processor and slide-mounting accessories. Optional features include a 4x5-inch film back, 8x10-inch film back, and 35mm motion picture back.

PhotoMetric SlideMaker from General Parametrics Corp.

The PhotoMetric SlideMaker is a desktop film recorder for the production of boardroom-quality 35mm slides. Features include: 4K addressability; full-color online preview; automatic text kerning for typeset quality; shaded (gradated) backgrounds; and automatic film loading, advancing, and exposure calibration.

Users can automatically shoot a single image, a series of images, or multiple copies of one or more images with no adjustments or exposure settings. A wide variety of popular film types are supported.

Bravo Computer Slide Maker (BCSM) from Polaroid Corp.

The Polaroid Bravo Computer Slide Maker (BCSM) is a digital film recorder capable of creating images with addressable resolutions of up to 8,000 lines. It has a palette of up to 16.7 million colors and produces both instant and conventionally processed boardroom-quality 35mm slides. Image resolution is software selectable.

The BCSM accepts Polaroid High Contrast PolaChrome instant color, Polaroid Presentation Chrome conventional, and other ISO 100 35mm slide films.

SlideWriter from Agfa Compugraphic Division

SlideWriter is a high-quality 35mm slide maker for business presentations, graphic design, image recording, and so on. Features include very

high-resolution 35mm slides (2,048 or 4,096 pixels per scan line),
virtually unlimited colors selectable from a palette of 16 million colors,
and fast recording.

AppleShare Network: WDEF Infection and Remedy

Our office has an AppleShare network with about 12 Macintosh nodes of varying configuration. The workstations are constantly going catatonic for about a minute at a time. They seem to be looking out onto the network for something (there's a network activity indicator under the Apple when this occurs), but all work is being done locally.

Almost any action can bring on the behavior. We're using a combination of LocalTalk and PhoneNet. Does this possibly sound like a problem with termination in the network cabling? I've used Inter*Poll to test performance, but can't locate any particular black hole on the net.

This article has been archived and is no longer updated by Apple.
It sounds more like you're dealing with the WDEF virus. The virus tries to infect a mounted AppleShare volume but, because AppleShare doesn't use the Desktop file, everything comes to a halt while WDEF figures out what to do.

We suggest running a good anti-virus utility on all your Macintosh systems except the file server. Symantec's SAM version 1.5 or higher will catch WDEF. You will want to eradicate the virus from your server (you'll have to start up with a floppy), but you don't want to install an anti-virus INIT on it, so that it runs all the time. You really wouldn't be keeping the server clean, just slowing it down.

You can remove WDEF without an anti-virus utility by simply rebuilding the Desktops on every Macintosh on the network. But be aware that you probably have several infected floppy disks around, just waiting to reinfect your hard drives. Also, if you work at home, you should check those computers for infection.

System 6.0.7: When It‘s Needed on Pre-LC Macintosh Models

I just got a copy of System 6.0.7. I know it is for the Macintosh Classic, LC, and IIsi, but does Apple recommend it for the Macintosh IIfx and the other Macintosh computers?

This article has been archived and is no longer updated by Apple.
System 6.0.7 is compatible with all Macintosh computers from the Macintosh Plus on up. The only time it is required on the older computers is if you're using an Extended Keyboard II (the one that comes with the Macintosh LC).

Published Date: Feb 18, 2012

MultiFinder: Why System Memory Fluctuates

Why does the amount of memory used by the System constantly change under MultiFinder or System 7? In the "About This Macintosh..." window, the System size and Largest Unused Block size fluctuate.

This article has been archived and is no longer updated by Apple.
This happens because of the event-driven operating system. As various events occur, the System may need to load or unload resources through RAM to take care of them. Because events happen all the time--even when the Macintosh seems to be idle--RAM allocation varies all the time.

You see this fluctuation under System 7 or MultiFinder and not under just the Finder (pre-System 7) because of the dynamic RAM allocation. Under Finder, all RAM allocation is fixed, whereas in MultiFinder and System 7 a given application or resource can request or free up RAM.

TA46316_Macintosh_WDEF_Symptoms_(TIL07668).pdf

Macintosh: WDEF Symptoms

I'm having the following problems under System Software 6.0.7:

* Repeated restarts when doing things (moving folders, files, and so on) on the desktop

* Flashing warning box with no text in the box

* System bomb with the error message "Address Error"

This article has been archived and is no longer updated by Apple.
There aren't any known problems with System 6.0.7, and especially none like that. We suspect that you're dealing with either a defective logic board or possibly a virus. I would suggest checking for the virus first, as the symptoms are similar to WDEF's infection of a Macintosh IIfx.

Published Date: Feb 18, 2012

LaserWriter IINT: Serial Connection to Xenix

I have a Macintosh IIcx and a LaserWriter IINT. I also have a Xenix network of four Sperry workstations. I am using a program called SCO Lyrix. This program has drivers that enable it to print to a PostScript printer. I want to print from one of these workstations to the LaserWriter IINT occasionally. Can I do this with the LaserWriter set for serial communication? What cable would I need to do this (or what are the pin-outs for such a cable)?

This article has been archived and is no longer updated by Apple.
This can be done serially; for a broad overview of the process, refer to Appendix of the LaserWriter Owner's Guide. Also check the Tech Info Library; search under "ibm" and "laserwriter".

There are two things to be aware after you get the other information. The first is that the manual is incorrect in stating that the LaserWriter requires 7 data bits; it should be 8.

Second, the easiest cable to make for this connection is as follows:

DB-25 LaserWriter
1 - 1
2 - 3
3 - 2
7 - 7

If you need hardware handshaking, add:

6 - 20

Published Date: Feb 18, 2012

MousePaint: Printing

MousePaint was designed as a black and white program, not a color program. While MousePaint will output to the Scribe in color, the quality is poor. The current version of MousePaint prints directly to Apple dot matrix printers only.
This article has been archived and is no longer updated by Apple.
For printing to third party printers such as Epson or Okidata, here are some indirect methods.

NOTE: All procedures reviewed here use the ProDOS /USERS.DISK that comes with the ProDOS supplied with Disk II's or with the ProDOS User's Kit.

1. Using an intelligent graphics interface: Grappler, Pkaso, or other.

    A. Save the picture by selecting the "Put a copy in..." command from the MousePaint File menu. This will create a standard binary picture file on a ProDOS-formatted data disk.

    B. Leave Paint.

    C. Start up Applesoft BASIC using the ProDOS /USERS.DISK. BASIC is an option on the main ProDOS menu.

    D. Now you must instruct your Apple to load the graphcs image and to tell the interface to dump it to the printer. Most graphics interfaces come with examples of programs that do this. Enter and save one of these on your ProDOS data disk.

Sales Tip: Enter the programs for the intelligent interfaces you support. Make sure they run under ProDOS and give them to your customers.

2. Using a "snapshot" interface.

Some cards, e.g., the "PRINT IT" interface, will print the screen when a button is pressed. Because you would print the Paint palette if you did a MousePaint screen dump, you should save the graphic as above and start up BASIC from the ProDOS /USERS.DISK. Then give these direct commands to your Apple:

```
HGR:POKE -16302,0
BLOAD picturename, A$2000
```

Then press the interface's button to dump the picture.

3. Making your Apple do the work.

This works if you have a graphics printing program that works with your printer, e.g., Printographer, Zoom Grafix, Apple LOGO Tool Kit and so on. Most of these programs run under DOS 3.3.

    A. Follow the instructions above to store a binary file on your ProDOS data disk.

    B. Start up the ProDOS /USERS.DISK.

    C. Now you must convert the binary file over to DOS 3.3 format using the CONVERT option on the ProDOS menu. Follow the instructions in the ProDOS manual for doing this conversion. (See our article on using the ProDOS CONVERT program for more information).

    D. After the file is converted to DOS 3.3, it may be loaded and dumped by your DOS 3.3 graphics program.

Of course, once these programs are published under ProDOS, you will not need to convert the binary file before using the graphics program.

To dump graphics, Apple IIc users can also employ the Imagewriter Tool Kit, Revision B, which works under ProDOS.

MacDraw II: Correcting Sluggish Object Moves

Periodically, when I select the object and move the mouse to the desired location, MacDraw II takes several seconds to snap the object to the new location.

The problem exists even when the computer is not connected to a network. I have re-installed MacDraw II version 2.0 and also re-installed the System.

This article has been archived and is no longer updated by Apple.

We haven't heard of this problem, but here are some diagnostic steps that may help:

1) Make sure no background processes are the cause. Remove INITs (screen dimmers, clocks, Sound Master, and the like).

2) Re-install the System software.

3) Try the same procedure on another system.

4) Check with Claris to see if they know of this situation.

Macintosh: Troubleshooting ID=15 Segment Loader Error

I have frequent system errors on a Macintosh II with internal CMS hard disk running Quark Xpress 3.0, Illustrator 1.9.x, and Aldus Freehand. The most frequent and consistent error is a System Error ID=15 (Segment Loader Error). It most frequently occurs when launching Quark Xpress by double-clicking a Quark document, although it has happened while opening documents from Illustrator and Freehand. Most of the time, launching the application using the "Open" command seems to work okay.

This article has been archived and is no longer updated by Apple.

It sounds like a software problem. What other files are in the System Folder? Try removing any added INITs (screen dimmers, sounds, mail, menu clocks, and the like). It may be that their software is fine, but when you combine this particular version of the system software with this particular version of Xpress you get a bomb. Make sure you are using a simple System Folder and the current versions of all the software.

Whenever you are troubleshooting a problem, always try to eliminate as many variables as possible. This would include eliminating third party hardware as well as any INITs or third party software that could affect the system folder.

Also, check with the software manufacturers for information on latest revisions, what version of the system should be used with what version of the application, and incompatibilities.

If problems continue after all software situations have been explored, look at hardware, particularly memory or memory management. The problem could be with RAM or the logic board.

LaserWriter IINTX: "offending command:font downloader" Message

I have a Macintosh IIcx with System 6.0.2 on a network with a LaserWriter IINTX. The NTX has an Apple SCSI hard disk. This configuration worked fine with 5.2 LaserWriter drivers and the 4.0 font downloader. However, when I load the 6.0 drivers, it downloads only the Times font and displays the PostScript error:

Invalid printer, offending command:font downloader

Now, with 5.2 drivers re-installed, it continues to mess up.

This article has been archived and is no longer updated by Apple.
This may or may not be the cause of your particular problem, but System 6.0.2 is not compatible with the Macintosh IIcx. The minimum software version is System 6.0.3, and we recommend running the System 6.0.5.

This problem sounds most like system software and/or driver corruption. We suggest you do the following things:

1) Run the Find File desk accessory ensure you don't have multiple System Folders on your hard drive

2) Regardless of how many System Folders you have, throw them all away after saving copies of any third-party INITs or CDEVs that you haven't backed up.

3) Use the Installer to install new System software and LaserWriter drivers onto the hard drive. Make sure the operating system version is at least 6.0.3.

Apple Licenses MS-DOS Connectivity Products To Farallon

Apple has entered into an agreement with Farallon Computing, Inc., granting them a non-exclusive, worldwide license to use, modify, create, develop, and market products from the AppleShare PC software and the LocalTalk PC Card.
This article has been archived and is no longer updated by Apple.
As a result of this agreement with Farallon, Apple has:

* Removed the AppleShare PC and LocalTalk PC products from its Finished Goods price lists in mid-March

* Transitioned to Farallon on April 1 the sales, service, and support for these products SOLD BY Farallon.

You should not have any difficulty distinguishing Apple's software and card from Farallon's, since products sold by Apple are stamped with an Apple logo, and products sold by Farallon have Farallon's trademark.

Farallon has renamed these products this way:

Apple Product	Farallon Product
AppleShare PC software	PhoneNET Talk software
LocalTalk PC Card	PhoneNET Card PC * LocalTalk Card

APPLE WILL CONTINUE TO PROVIDE SERVICE AND SUPPORT (INCLUDING MEDIA EXCHANGE) FOR APPLESHARE PC AND LOCALTALK PC PRODUCTS SOLD BY APPLE PRIOR TO APRIL 1, 1991. Service Providers should continue to service and support these products through Apple.

For more information, search on "Farallon".

Apple Scanner: Clarification to Page 121 of the Owner‘s Guide

I'm having trouble scanning according to the directions on page 120 and 121 in the Apple Scanner Owner's Guide. While the directions are clear on how to define two separate areas, it seems I can only select one composition for the whole page.

For example, following the instructions, I select the first area and choose the halftone composition. Then, using the Scan Area tool, I choose the second area and select the line art composition. If I click back on the first area, the composition is at line art, not halftone. If I click it back to halftone and go to the second area, the second area switches to halftone.

Does this feature really work using the AppleScan software? What am I doing wrong?

This article has been archived and is no longer updated by Apple.

We set up the Apple Scanner and followed the directions on page 121. We got two images--one half-tone and one line art--on the screen at the same time. Be sure to select the arrow tool so that things get reset before selecting the scan area tool the second time. Then select the scan area tool and line art before scanning the document.

HyperCard: How To Do ASCII Character Sorting

I want to create a list in HyperCard that contains foreign characters (meaning characters with accent marks, and so on). I can't seem to get HyperCard to sort the characters correctly. Doesn't HyperCard use a standard ASCII table to sort characters?

This article has been archived and is no longer updated by Apple.
HyperCard sorts text using the assigned ASCII values for each character. This means that ascending sorts put text symbols first, followed by numerals, then alphabetic characters last. A sort command that will work for you is:

"sort ascending text by expression"

where "expression" is any expression.

Macintosh: Problems with Large Startup Screens

Is there a startup screen size limit? I've created a 1MB startup screen for my Macintosh, but my system keeps hanging at startup.

This article has been archived and is no longer updated by Apple.

There is no set startup screen limit, but you may be running out of RAM. Your limiting factors are available RAM and heap size. You need to have enough RAM to load your System file, Finder, any INITs or CDEVs, and any RAM cache that might be set in your control panel.

Another possibility could be your system heap needing resizing to accommodate such a large startup screen. Apple does not support changing the heap size, but there are several third-party utilities that do this.

For more information, search on "CE Software".

Macintosh: Startup Screen Color Shifts Caused by CLUT Matching

When the startup screen on my Macintosh appears, it is first dark and then seems to lighten in tone. Why is this happening?

This article has been archived and is no longer updated by Apple.
The changes to the display of your startup screen are caused by the color look-up table (CLUT). The Macintosh has many color combinations available. For example, on an 8-bit system, there is a choice of 256 colors out of 16 million possibilities. The computer stores a color look-up table for a startup screen graphic, and what you're noticing is the time it takes the Macintosh to match the graphic to the CLUT. During this matching, there is also a shift in the intensity of colors displayed in the graphic.

Apple Tape Backup: Workaround to Exact Size Volume Limitation

I'm unable to do a volume restore to a different size drive using the Apple Tape Backup 2.0.1. Is there any workaround to the exact size requirement of Apple's backup software?

This article has been archived and is no longer updated by Apple.
The Apple Tape Backup does insist on restoring to a volume that's the exact size of the original.

There is a way around this (it works only if your backup is a volume backup). An INIT called Tape Disk comes with Tape Backup 2.0.1. Install this INIT into your System Folder and restart. Your tape will show up on the Desktop--just like a drive icon. You then simply drag over any files you want to the hard disk.

ImageWriter and Dot Matrix Printers: Setting Page Lengths

This article has been archived and is no longer updated by Apple.
You can set custom page lengths for the Imagwriter and Dot Matrix printers by sending a string of continuous text to the printer. This string sets the number of printed lines per page and the number of lines between the current BOF (bottom of form) and the following TOF (top of form). The commands that need to be entered are as follows:

COMMAND STRING DECIMAL EQUIVALENT FUNCTION

control]A@ 29 65 64 Set TOF

@@ 64 64
At this point you would enter the command @@ for each printed line of text, less two. For example, to set a length of 44 lines, you would enter the string @@ 42 times with no spaces.

C@ 67 64 Set BOF

@@ 64 64
At this point you would enter the command @@ for each line between the current BOF and the next TOF. For example, if you need to skip 10 lines to bring you to the next TOF, then you would enter the string @@ 10 times.

A@control^ 65 64 30 Set TOF
Next Page

A program to produce these strings will ensure the needed accuracy in the character string. Once the page length has been set, it will remain in effect until the printer power is turned off. If you need more information, refer to the Imagewriter and Dot Matrix Printer Reference Manuals under the headings of Setting Page Length and Vertical Tabbing.

HyperCard IIGS: Release Information

When is Apple going to release HyperCard for the Apple IIGS?

This article has been archived and is no longer updated by Apple.
Apple announced HyperCard¿ IIGS¿ for the Apple IIGS¿ personal computer in December 1990. The program was made available in February 1991 through authorized Apple dealers in mid-February 1991. The program comes with nine ready-to-use stacks.

HyperCard IIGS has the full functionality of Macintosh HyperCard version 1.2.5--plus enhancements to improve performance and take advantage of the color capabilities built into the Apple IIGS. Users can also access the many stacks that already exist for the Macintosh, once developers convert them for the Apple IIGS.

To use HyperCard IIGS, you need an Apple IIGS with at least 1.5MB of RAM (2MB is recommended), system software 5.0.4 or later, one 800K disk drive, and a hard-disk drive (or connection to a network). HyperCard IIGS is sold only as a stand-alone kit with six program disks and three manuals.

AppleShare PC: No Support for DEC Ethernet Card

I have a DOS clone with a DEC DEPCA-AA Ethernet card. Does AppleShare PC support this card, or will I have to get a different card.

This article has been archived and is no longer updated by Apple.
The DEC DEPCA-AA Ethernet card is not inherently supported by AppleShare PC. The list of supported Ethernet cards in the Technical Info library states that the 3Com EtherLink II and its MicroChannel-equivalent card are the only supported Ethernet cards.

However, since "Farallon" took over both AppleShare PC as well as the LocalTalk PC Card from Apple in April 1991, you should contact them for the most current information since they have updated the software to support more DOS programs as well as other hardware.

Disk First Aid and MFS Volumes

I'm trying to run Disk First Aid version 1.4.2 from a bootable floppy. When I run the program to analyze my hard disk it says "This is not an HFS disk" (and I think it is).

I'm doing this because Symantec said to run Disk First Aid before trying to defragment and optimize my hard disk before running "Disk TuneUp" on SUM II.

This article has been archived and is no longer updated by Apple.

We have seen this error only when trying to run Disk First Aid on an MFS-formatted volume. You can verify that the volume is HFS by looking at the left side of the two lines below the volume information when your disk window is open. There will be a pixel on the left side indicating that the volume is an HFS volume. The absence of a pixel means you have an MFS volume or you are running System 7.

If the volume is HFS, use a more current version of Disk First Aid--version 1.4.3 or above.

Published Date: Feb 18, 2012

Applesoft Internals: String Utilities

Applesoft strings have two parts: the descriptor and the ASCII string. Your string descriptor contains the length of the string along with the address of the strings first character.

Refer to page 137 of the Applesoft Reference Manual for additional information on the string components.
This article has been archived and is no longer updated by Apple.
During most Applesoft routines the descriptor is left in memory, while a two byte pointer to the descriptor is kept in the FAC. The pointer is the address of the descriptor; therefore, the actual string could be anywhere in memory. The statement 10 A$ = "HI" leaves a descriptor pointing to the program text.

STRINI ---- E3D5
STRINI obtains space for creating a string whose descriptor is pointed to by FACMO/FACLO; it also creates a descriptor for it in DSCTMP. On entry A = length of the string, while FACMO/FACLO point to the string descriptor.

STRINI uses GETSPA to force garbage collection when there isn't sufficient room; GETSPA exits with an "OUT OF MEMORY ERROR" when garbage collection free up enough room. GETSPA moves FRESPC and FRETOP down, making room to store the string. STRINI returns with the descriptor of the new string in DSCTMP and the original pointer in DSCPNT.

STRSPA ---- E3DD
STRSPA obtains space for the creation of a string A bytes long, then creates a descriptor for it in DSCTMP. STRSPA uses GETSPA to force garbage collection when there isn't enough room. If garbage collection is unable to make sufficient room, GETSPA exits with an "OUT OF MEMORY" error. GETSPA moves FRESPC and FRETOP down enough to store the string, then returns A unchanged with the new descriptor in DCSTMP.

GETSPT ---- DA7B
GETSPT moves the descriptor pointed to by FACMO/FACLO into the memory pointed to by FORPNT. GETSPT also moves the string's text up to FRETOP if it isn't in the program's text. GETSPT frees up the string if it was a temporary string. GETSPT uses GETSPA to initiate garbage collection, or alternatively "OUT OF MEMORY" error when the garbage collection dosen't free up sufficient room.

MOVINS ---- E5D4
Moves the string whose descriptor is pointed to by STRNG1 to memory pointed to by FRESPA.

MOVSTR ---- E5E2
MOVSTR moves the string pointed to by Y,X with a length of A to memory pointed to by FRESPA.

STRTXT ---- DE81
Build a temporary descriptor for a string literal of which the first character is pointed to by TXTPTR plus C and which ends with a quote. FACMO,FACLO points to the resulting temporary descriptor. Skip leading quotes before calling STRLIT. On exit, STRNG2 points to the character after the string literal.

STRLIT ---- E3E7
Build a temporary descriptor for a string literal of which the first character is pointed to by Y,A and which ends with a quote. FACMO,FACLO points to the resulting temporary descriptor. Skip leading quotes before calling STRLIT. On exit, STRNG2 points to the character after the string literal.

STRLT2 ---- E3ED
Take a string literal of which the first character is pointed to by Y,A and build a temporary descriptor for it pointed to by FACMO,FACLO. Save in CHARAC and ENDCHR the characters other than zero that terminate the string. Skip leading quotes before calling STRLIT2. On exit, STRNG2 points to the character after the string literal.

PUTNEW ---- E42A
Move the descriptor in DSCTMP to a temporary descriptor, put a pointer to the descriptor in FACMO,FACLO, and flag the result as a string.

GETSPA ---- E452

Get A bytes of memory below HIMEM for a string. GETSPA forces garbage collection to make room in memory when necessary and exits with an "OUT OF MEMORY ERROR" if garbage collection can't make enough room. GETSPA moves FRESPC and FRETOP down enough to store the string. On entry, A equals the number of characters. GETSPA returns with A unchanged and pointer to the space in FRESPC, FRETOP, and Y,X.

FRESTR ---- E5FD
Make sure that the last FAC result was a string and free up the temporary string result. Check the descriptor for a temporary status allocated by PUTNEW. On exit, the address of the string is in INDEX and Y,X. The length of the string is in A. Uses FRETMP.

FREFAC ---- E600
Free up the temporary string pointed to by FACMO,FACLO. Check the descriptor for a temporary status allocated by PUTNEW. On exit the address of the string is in INDEX and Y,X. The length of the string is in A. Uses FRETMP.

FRETMP ---- E604
Free up a temporary string. On entry the pointer to the descriptor is in Y,A. Checks the descriptor for a temporary status allocated by PUTNEW. If so, the temporary is freed up by updating TEMPPT. If a temp is freed up, a further check tests the string's location for the lowest in memory. If so, that area of memory is freed up by updating FRETOP. On exit the address of the string is in INDEX and Y,X. The length of the string is in A.

FRETMS ---- E635
Free the temporary descriptor without freeing up the string. On entry Y,A point to the descriptor to be freed. On exit Z is set if anything was freed.

System 6.0.5: Troubleshooting Mouse Problem

Article Reviewed Only: 10 July 1992

The pointer freezes in the left corner of the screen when I start my Macintosh IIcx under System 6.0.5. If I start with System 6.0.3, the problem goes away.

This article has been archived and is no longer updated by Apple.
One problem with System 6.0.5 is that, if the connection is somewhat shaky, the system does not recognize the mouse after startup. If you run pre-6.0.5 System software, you can start the machine without the mouse, wait for it to complete the boot process, and then plug the mouse in. The system will recognize the mouse immediately.

We suggest that you try these diagnostic steps:

1) Verify the mouse connection to the keyboard or back of the machine.

2) Start the machine with the mouse plugged into the connector not currently in use.

3) If there is no difference, try throwing away the currently-installed System folder and reinstall a new copy, using the Installer.

PrintServer and AppleShare 2.01

I am rebuilding an AppleShare network from scratch. I am upgrading many of the files that we had previously used. The file server seems to be working okay but there are a few problems. I have rebuilt with System 6.0.5 (we had previously used 6.0.3), AppleShare 2.01, and Printserver 2.0. The network is running on a Macintosh SE with 2.5MB RAM.

The network starts okay, but has crashed several times. I think most of these crashes are due to system incompatibilities or memory problems in the workstations. The workstations are mostly Macintosh SEs with 1MB. I expected some of the applications (like PixelPaint and Studio/8) to bomb, because of memory, but these have also caused the file server to crash. One user caused a crash by typing a new password. I thought this was due to system incompatibility (he's running 6.0.3 at present), but the documentation for 6.0.5 says it works fine in a network with other systems (specifically 6.0.2, 6.0.3, and 6.0.4).

The biggest problem I am having is with the PrintServer. I installed it, but when I load it and try to connect to a network printer, it times out. (I have tried both printers on the network with the same results. I have also re-installed PrintServer from another set of diskettes.) Then, when you choose to quit the application it bombs the system.

Do you know of any incompatibilities among System 6.0.5, AppleShare 2.01, and PrintServer 2.0? Are there any upgrades I might need? How about the RAM cache, now set for 1MB? Also, does AppleShare get upset with the file server running 6.0.5 and workstations running an earlier version?

This article has been archived and is no longer updated by Apple.
We don't know of any incompatibilities with the system software and application versions you have listed. In fact, we run similar configurations with no difficulty.

The RAM cache is not changeable by the administrator on an AppleShare server. Rather, AppleShare dynamically allocates RAM to meet its needs. Don't change anything in the RAM cache.

We have two concerns with your configuration:

* Are all your users running the same version of the LaserWriter drivers?

* Was the System software installed using the Installer -- not drag copied?

It is very important that you run the Installer, because this is the only way to get the proper ROM patches loaded into the individual computer's System file.

With your Print Server, you mention that when you load it and try to "connect to a network printer", I have to assume that you are capturing a printer for print spooling services. If that is correct, and it times out, you may want to look at using the 6.0.1 LaserWriter and Laser Prep files as this timeout problem was addressed in those drivers. If you do use these drivers, make sure that all users upgrade and that there are no older drivers present in the network.

3270 Dial-In for the Macintosh: Use MacTerminal

Can my Macintosh dial in remotely to an IBM 3708 and get 3270 terminal emulation? Is there a Macintosh equivalent to FTTerm, a DOS product that does this on the IBM?

This article has been archived and is no longer updated by Apple.

3270 emulation is available from the Macintosh side with MacTerminal. This is Apple's data communications product and should work just fine in this environment. You will need to verify with the network administrator that there is the capability in the host for remote dial-in support. If so, have it set up on the host and you should be in business.

AppleShare File Server: When You Can‘t Throw Away Files

When I'm logged on as the Administrator of my AppleShare server, the system locks up and bombs whenever I try to throw away folders with duplicate data in them. If I go to the file server and start up with an AppleShare Admin Disk, I can throw these folders away.

This article has been archived and is no longer updated by Apple.
The locking up and bombing problem while throwing away folders could be caused by a couple of things. Try these steps:

1. Rebuild the desktop by holding down the Command and Option keys while the system is starting up from a floppy disk.

2. If the problem persists, reinstall the System and AppleShare software, as there may be some pointers to the Desktop and Finder that could be corrupted. This would explain why files can be thrown away when booted from a floppy.

3Com INIT and AppleTalk System File

I have encountered a problem involving 3Com's 3+Mail, the 3+File, and the AppleTalk system file. It seems that 3Com or something is modifying the AppleTalk file so that the Macintosh bombs (usually ID 3). Throwing out the AppleTalk system file prevents the system crash, and my Macintosh seems to run just fine without the file.

What creates this file? What does it do? Why do I need it?

This article has been archived and is no longer updated by Apple.

```
The file contains AppleTalk protocol updates.  AppleTalk is found in ROM,
but when an update is made to AppleTalk, these changes get put in a system
file. This could happen if you're doing a number of system-related
installations:  3Com, EtherTalk, System, etc.

The 3Com INIT is, unfortunately, not "smart" enough to say "I'm not on,
EtherNet, so don't load yet."   If you forget to disable the 3Com INIT and
you boot with LocalTalk selected, you will get a bomb and have to boot from
another disk to start up.
```

Macintosh: Advanced Cut & Paste Tips for Multiplan & MS-BASIC

This article has been archived and is no longer updated by Apple.

A limited number of fonts are available in Multiplan; it does, though it have several print options, including (a) printing with or without coordinates, (b) printing with or without cells, and (c) printing in condensed or draft form. If you wish, you can vary the font used in Multiplan by moving the text into a MacWrite document:

1. Simply cut or copy the desired cells.
2. Quit and eject Multiplan.
3. Without rebooting, insert the MacWrite disk.
4. Start up an application.
5. Paste in your model.
6. Customize the type style of the text as you wish.

MacPaint also accepts graphics created in MS-BASIC. To move such a document into MacPaint:

1. Enlarge the MS-BASIC output window to its full extent.
2. Run your graphics program.
3. Key in SHIFT-COMMAND-3. This dumps the screen to disk.
4. Open and modify the resulting Screen file in MacPaint.
5. Move the MacPaint document to MacWrite.

Though the MS-BASIC editor only uses the clipboard for single lines, MS-BASIC programs can write many lines of text to the Clipboard. At present, MS-BASIC does not write graphics to the Clipboard, but it does have text-only access to the Clipboard's facilities through the device name CLIP:. Here is a pair of programs to demonstrate the use of CLIP:; note that the programs do file I/O with text created by the program.

```
10 REM Writes to Clipboard 10 REM Gets data from Clipboard
20 Open "CLIP:" for output as #1 20 Open "CLIP:" for input as #1
30 For i=1 to 10 30 While not EOF (1)
40 Write#1: ,"Hi, I'm Macintosh!" 40 Input #1,A$
50 Next i 50 Print A$
60 Close #1 60 Wend
70 Close #1
```

You can also use MS-BASIC to manipulate Multiplan data. The working solution elaborates upon the Clipboard example shown above. See Appendix H of the MS-BASIC manual for more details.

AppleCD SC: Operating Temperature Without a Fan

A customer is concerned about the compact disks getting a bit warm to the touch now that the fan is disconnected. Is this normal? And if so, how warm can the player get?

This article has been archived and is no longer updated by Apple.

It is true that the temperature of the unit rises without the cooling fan. Apple did a considerable amount of testing and found that the temperature remained lower than the 120+F needed to warp a CD. With the fan removed pay close attention to the unit's ventilation. DO NOT stack anything on top of the unit.

AppleShare IP 6.3/Apple Remote Access Personal Server 3.5: Server Stops Responding ("Hangs") When ARAP Client Disconnects

On an AppleShare IP 6.3 server with an internal modem running Apple Remote Access Personal Server 3.5, the server may stop responding when the client disconnects.
This article has been archived and is no longer updated by Apple.

Symptom

On an AppleShare IP 6.3 server with an internal modem running Apple Remote Access Personal Server 3.5, the server may stop responding when the client disconnects. This happens most often when the client connects via ARAP (Apple Remote Access Protocol), though it can also occur via PPP. It does not occur with an external modem.

Solution

Use an external modem on the server.

Macintosh: Microsoft BASIC program merging

This article has been archived and is no longer updated by Apple.

When merging MS-BASIC programs with the MERGE command (see p. 119, MS-BASIC manual), care must be taken with the program to be merged with the program in memory: make sure that you have saved IN ASCII FORMAT the program to be merged. Make sure also that the line numbers of both programs do not overlap or repeat, because the MERGE function overwrites the lines in memory with lines from the disk file that have matching line numbers. To avoid the problem, renumber the program in memory with the RENUMB command described on p. 154 of the MS-BASIC manual.

DEC LQPO2 Daisy Wheel Printer: Pinouts for Macintosh

I'm trying to hook up a Digital LQP02 serial daisywheel printer to a Macintosh SE.

The pin-outs are:

LQP02 Digital Macintosh SE

Pin # Pin #
1 shield 1 HSKO
2 Tx data 2 HSKi
3 Rx data 3 TxD-
6 Data Set Ready 4 GND
7 Signal ground 5 RXD-
20 DTR 6 TxD+
7 GPi
8 RxD+

Which pins goes to which connection?

I understand that the grounds go together. What about the shield? Do I really need it? The Tx goes to Rx, but the + and - TxD, RxD on the Macintosh side was a little confusing.

This article has been archived and is no longer updated by Apple.

Use the negative TxD and RxD on the Macintosh side. Also, use the shield.

Macintosh: Large Amounts of Clip Art

I'd like to have a single file with all my clip art in it so that I can quickly find and copy pictures to the Scrapbook. What program would be best at doing this?

This article has been archived and is no longer updated by Apple.
There is no single right answer to your question. What application you should use depends on the file format of your graphics.

If you are using PostScript clip art, you'll need an application that works in PostScript, such as Adobe Illustrator or Aldus Freehand. If you are going to work with PICT documents, you'll need an application such as MacDraw II. If you are going to work with bit-mapped graphics, a program such as SuperPaint or MacPaint will suffice.

You may want to look for a program that is an art catalogger. These are generally used by people in the Graphics and Design section of desktop publishing who have large amounts of clip art that is commonly used.

Probably the best suggestion is to contact the company whose program you are using, and ask them what catalogger works best with their software or the respective type of clip art or graphic. An example would be to contact Adobe if you are using Illustrator, or Aldus if you are using Freehand.

Apple III: Switch Settings for Apple DMP

What are the switch settings for connecting an Apple III with a UPIC to an Apple DMP?

This article has been archived and is no longer updated by Apple.
Here is the recommended configuration:

DMP
SW1 1 off
2 off
3 off
4 off
5 off
6 off
7 off
8 off

SW2 1 off
2 off
3 XX (not used)
4 XX
5 off
6 on
7 on
8 off

UPIC with cable 590-0036.

Driver configuration block - Printer Driver

0 1 2 3 4
0E 00 00 00 00

Set the auto linefeed switch on the UPIC to AUTO.

Hard Drives: Sticking At Startup

I have an older Macintosh LC with an external 40 megabyte (MB) hard drive. Sometimes when I switch the external drive on, it will not start spinning. Tapping the side of the hard drive seems to break something loose inside, and the drive then starts spinning. The drive may work fine for a while, but the problem generally occurs again. Is there something wrong with my hard drive?

This article has been archived and is no longer updated by Apple.

This is one of the most common hard drive failures. When a hard drive spins down, the read/write heads land on the platters. Hard drive manufacturers place some lubricant on the platters so that the heads don't scratch the platter surfaces when the drive is switched on again. Sometimes the lubricant actually functions as an adhesive and sticks the read/write heads to the platter. If the spindle motor can't overcome this adhesion, the hard drive will not spin up. The hard drive industry refers to this condition "stiction." A twist or a bump may free the heads temporarily, but the condition usually recurs. If you have a hard drive exhibiting these symptoms, back up any data that may not have been backed up, because the hard drive is not reliable. The repair is usually a drive replacement.

This is an industry-wide problem. Hard drive manufacturers are exploring alternate forms of lubrication and read/write head placement methods.

AppleFax Modem: When Wrong Size Letter Is Sent

I have an AppleFax modem that always sends European letter-size faxes instead of regular letter-size.

I have re-done the setup three times, step-by-step, with no luck. Could this be a ROM problem?

This article has been archived and is no longer updated by Apple.
It is possible that there is a ROM problem with your AppleFax Modem. There was a ROM upgrade for the AppleFax and you should order it.

If that still does not cure the problem and all your settings have been checked and verified, the logic board probably is the cause of the problem.

Apple SuperDrive: Requires System 6.0.3 or Later (10/94)

I am using DOS mounter and an Apple SuperDrive (formerly Apple FDHD) attached to a Macintosh SE. When I insert a 720K or 1.44MB DOS disk, the disk doesn't mount. Using Apple File Exchange doesn't help.

Is there a specific Apple System version necessary to operate the SuperDrive?

This article has been archived and is no longer updated by Apple.
For the best use of the SuperDrive, we recommend System software 6.0.3 or later.

Apple IIGS: 03 ROM Upgrade Not Needed by Older Machines

Is there a new revision or ROM upgrade available for the Apple IIGS?

This article has been archived and is no longer updated by Apple.
The current version of the Apple IIGS ROM is 03. We have not offered an upgrade for ROM 01 owners. Most of the changes that came out in version 03 are for the 1MB logic board, hence the new ROM would be of little help to older Apple IIGS owners.

Macintosh: Disk Recovery

This article has been archived and is no longer updated by Apple.

At the outset, we recommend that you and your customers practice that time-honored tradition of backing up important files. Recently, however, we have gotten suggestions on reviving damaged Macintosh application disks and retrieving files from damaged data disks. Since there are many ways to blow up disk directories, though, these methods are not 100% effective.

Method one: Rebuild the desktop file.

1. If the disk is bootable (i.e. has a system folder on it), put the bad disk into the internal drive while the Macintosh is turned off.
2. Hold down the OPTION and COMMAND keys and turn the Macintosh on.
3. While the Macintosh boots, hold down the OPTION and COMMAND keys until the disk icon appears.
4. If the disk is a data disk (i.e. no system folder on it) then boot the system with a good disk. When the data disk is inserted into the drive hold down the OPTION and COMMAND keys as above.

This method sometimes requires several attempts, and while it restores data files, file folders are lost on Finders prior to 4.1; they must be re-created, and the documents must be placed back into them manually. If the Finder is version 4.1 or greater then the folders lose their names and must be manually renamed.

Method two: Recovering files.

1. Boot the Macintosh with a good copy of the application needed to read the data files you wish to recover.
2. Create a new document in that application with a double click on the application's icon.
3. Once the document, usually called "Untitled", has opened, close it.
4. Select Open on the File menu.
5. Insert the bad disk.
6. Select Open again and try to read files off of the bad disk.
7. Save the files to a good disk.

This method also works faster if you use a second drive for reading data files.

Method three: Replacing System Files.

This method has been known to work with disks that fail to boot and exhibit a "Sad Macintosh" with the address 0F0064. First attempt Method one above. If that doesn't work, boot from a good disk and then insert the bad one. If the bad one appears on the desktop, then throw away the bad disk's System Files and replace them with new ones from the good disk.

AppleShare File Server: Making Files Undeletable

Is there any way to make a file undeletable on an AppleShare file server? I'm aware of the lock attribute, but I need something that a workstation user could not change easily.

This article has been archived and is no longer updated by Apple.
There are a couple of commercial file protection programs that would allow you to lock files and make them undeletable.

For more information, check the Redgate Buyers Guide library on AppleLink.

Apple HD SC Setup: Checks for Bad Blocks And More

Does the Apple HD SC Setup program re-map the hard disk to set aside bad or unusable sectors like a low-level format, or does it simply set up blocks and mark them all as available?

What other hard drive issues can it address?
This article has been archived and is no longer updated by Apple.
Yes, Apple HD SC Setup does spare bad blocks. If too many bad blocks are found, a message that the hard drive needs to be serviced is displayed. Since you were apparently able to format the drive successfully, we can assume that the problems are not due to bad blocks.

The drive could be have other errors though. For instance, it could be having trouble positioning its head on the platters.

In very rare cases a third party formatter used on a Apple drive can damage it so that Apple HD SC Setup will no longer recognize it. The hardware is usually OK but the driver is severely corrupted. This was an issue with older version of Apple HD SC Setup and should not occur with the version shipping with System 7.5.

If you can prevent the driver from loading at start up. You can usually get Apple HD SC Setup to recognize and reformat the drive. To prevent the driver from loading, wait till the Mac has booted before turning on the drive. For internal drives, try holding down CMD-OPT-SHT-DELETE until the Mac has booted. (Note: This does not work on most Quadra, PowerBook, or LC series computers.

A good rule to follow is to format all SCSI devices with the same formatting software. This avoids possible SCSI driver conflicts.

With System 7.5, all 68040 based and higher Macintosh computers need to have SCSI Manager 4.3 compatible drivers.

You can also do a "Get Info" on problematic drive. In the Get Info window, next to where is says 'Where:' you will see "Hard Disk Name, SCSI 0" or "HardDiskName, SCSI 0 (a)" if it is an Apple HD SC Setup formatted drive. If any other information/characters are there, then it has a third party driver.

Macintosh IIci: Built-In Video Slows Performance Slightly

Does the Macintosh IIci's built-in video port support all Apple monitors?

Does using built-in video, instead of a separate video card, slow the performance of the Macintosh IIci?

This article has been archived and is no longer updated by Apple.
The Macintosh IIci's built-in video port supports the Apple High Resolution Monochrome, the Apple High Resolution RGB, and the Apple Portrait monitor. It does not support Apple's 2-page monitor.

Using the built-in video port instead of a card requires the computer to use its system memory for screen drawing, resulting in a loss of some performance. This can be minimized by using at least 5MB of RAM with the 1MB bank being located in bank A for video use.

TA46366_Apple_IIGS_Using_on_AppleTalk_Phase_II_Network_(TIL07735).pdf

Apple IIGS: Using on AppleTalk Phase II Network

I'm running an Apple IIGS, with GS/OS 5.02, on an AppleTalk LAN with a "II bootblocked" AppleShare server.

Can I upgrade this network to AppleTalk Phase II? I assume that if I do, my Apple IIGS computers will boot from a server in their own zone. What if I want to have two servers in one physical zone? Where will the Apple IIGS computers boot from?

This article has been archived and is no longer updated by Apple.
AppleTalk Phase II has no effect on LocalTalk. The enhancements that Phase II provides are only for EtherNet and Token Ring

There was an upgrade to the boot blocks for loading GS/OS on the server. This is included with GS/OS 5.02 on a new Apple II setup disk.

The Apple IIGS will boot from the first server it finds.

AppleShare & Apple IIGS: "Cannot Load Descriptor File" Error

I have a problem trying to install an Apple IIGS workstation on an AppleShare network.

On my Macintosh SE/30 file server, I've installed System 6.0.5, AppleShare, and Apple II network software. On my Apple IIGS, I made an "AppleShare on 3.5" startup disk, started it up, logged on, and installed Network Server Startup on the file server. After starting the Apple IIGS up from the network and setting the startup application to the Finder, I got the error message, "CANNOT LOAD DESCRIPTOR FILE $0001." I've re-installed everything and the problem persists.

This article has been archived and is no longer updated by Apple.
This sounds like an AppleShare server access privileges problem. Set the System Icons privileges to see files and folders for everyone and make sure that this change is made for all enclosed folders.

ImageWriter II: Switch Settings for Use with a Apple IIe

What are the proper settings for using an Apple IIe with a Super Serial Card to an ImageWriter II?

This article has been archived and is no longer updated by Apple.

```
The settings should be:

Super Serial Card
SW1  1  off
    2  off
    3  off
    4  on
    5  off
    6  on
    7  on

SW2  1  on
    2  off
    3  off
    4  off
    5  on
    6  off
    7  off

Jumper  block pointed toward terminal.

ImageWriter II
SW1  1  off
    2  off
    3  off
    4  off
    5  off
    6  on
    7  off
    8  off

SW2  1  on
    2  on
    3  off
    4  off

Cable:  590-0335 or 590-0556
```

AppleShare: Installing on Systems that Require System 6.0.4

I recently purchased a Macintosh IIci as an AppleShare file server. My version of AppleShare File Server (2.0.1) is on an 800K diskette and cannot be used because it does not have System Software 6.0.4 on it. Is my only alternative copying the applications to a 1.4MB diskette that has System 6.0.4 on it?

This article has been archived and is no longer updated by Apple.
In order for you to install AppleShare or some of our other networking and communications software on our newer computers, use the Network Products Installer diskette. This disk contains the latest System software and installer scripts as a pre-boot for the actual installer diskette. Just boot from the NPI disk, launch the particular Installer script, and the Installer will prompt you for the appropriate diskette.

The NPI diskette is currently shipping with all new systems that require System 6.0.4 or higher.

Isolation Transformer: How It Protects You from Shock

How does the isolation transformer protect a service technician from getting shocked?
This article has been archived and is no longer updated by Apple.
The isolation transformer protects against a ground that's been reversed with a hot lead: for example, a normally grounded monitor frame that's been switched to hot. If you were to touch the frame and a true ground, you would be severely electrocuted.

The isolation transformer creates a floating source for the voltage that ties the voltage coming from the transformer to earth ground. This prevents you from getting between the power source and ground to complete a circuit.

ADB Devices: Don‘t Connect/Disconnect while Computer Is On

I usually run my AppleShare servers without attached keyboards. When a keyboard is needed, I simply connect it. Recently, I've noticed that if the keyboard is plugged in after the machine is booted, the keyboard doesn't work. This problem seems to happen with newer machines and/or the newer versions of the system software.

This article has been archived and is no longer updated by Apple.

The Apple Desktop Bus (ADB) was never intended to allow power-on configuration changes. This is a dangerous practice, as the ADB fuse is a soldered component on the logic board: if the fuse blows from connecting or disconnecting keyboards (or mice, trackballs, etc.) -- the logic board will need to be replaced. The owner's manuals have always made this clear.

LaserWriter IINTX: Trouble Initializing Attached Hard Drive

My LaserWriter IINTX is connected to an Apple 40SC Hard drive. My hard drive's SCSI ID is set to 5 and is properly terminated. When I attempt to to initialize the hard disk using the LaserWriter Font Utility, the initialize button is always greyed out.

This article has been archived and is no longer updated by Apple.
Be sure that you have:

* Connected the drive to the 50-pin SCSI connector instead of the DB-25 port serial connector on the I/O board.

* Not connected your computer to the same SCSI bus as the printer and the hard drive.

* Let the drive become ready before turning on the LaserWriter IINTX.

If all the above are correct, you may have a bad LaserWriter IINTX controller or hard drive mechanism.

LaserWriter: Timeout Error Messages Printing Long Documents

When I try to print out long documents on my LaserWriter, I get a timeout error message. Someone suggested that I change the default values of my timeouts with a PostScript program. Where can I get such a program? What else can I do with it? Is one program better than another?

This article has been archived and is no longer updated by Apple.
The new LaserWriter drivers (6.0.1 and later) are better at handling longer print jobs. If you are using older drivers, upgrade to the 6.0.1 versions as a first step.

The PostScript "program" you refer to is not an off-the-shelf commercial product. It's a PostScript code sequence that changes the default value of the timeout clock. We recommend looking at the PostScript Language Reference manual, published by Addison-Wesley. This book explains using PostScript commands to alter the timeout.

We recommend against sending PostScript commands to the LaserWriter, as it is quite possible to change the LaserWriter's parameters in such a way as to make the LaserWriter permanently inaccessible.

For more information, search on "Addison-Wesley".

AppleShare File Server: Cannot Be Bypassed at Startup

Is there any way to prevent an AppleShare file server from starting up AppleShare that doesn't require using a separate system disk? Is there an option key sequence, for instance?

This article has been archived and is no longer updated by Apple.
There is no hot key you can use to bypass AppleShare at startup. Using a separate system disk is the only way to prevent AppleShare from loading.

Macintosh: "Sad Macintosh" Error Code Meaning

This article lists and explains the error codes that accompany the "sad Macintosh" icon that appears on the screen when a Macintosh computer does not start up.

This article has been archived and is no longer updated by Apple.

Products Affected

The "sad Macintosh" icon and its associated error codes exist only in older Macintosh computers. Newer models, such as those with Universal Serial Bus (USB) or Open Firmware, use a different mechanism for reporting such failures. For more information on newer systems, please see the following articles:

Article 58183: "**Power-On Self-Test Beep Definition - Part 1**"
Article 58442: "**Power-On Self-Test Beep Definition - Part 2**"
Article 95036: "**Power Mac G4: Power-On Self Test**"

Overview

The particular error code that appears with the "sad Macintosh" is not as important as **when** it occurs. If the Macintosh can start up from a different system disk then the fault is probably with the system software on the other disk. System faults are usually identified when you get a "happy Macintosh" face and the "Welcome to Macintosh" screen before the "sad Macintosh."

If the "sad Macintosh" appears immediately when you turn on the computer, that usually suggests an issue with the logic board or memory. Try starting up from a floppy disk before assuming it is a hardware fault.

Sad Mac Error Codes Description

On the Original ROMs (Macintosh 128K 512kK 512kK, Plus):

When you press the interrupt button on the side of your Macintosh when starting up, a sad Mac icon on the screen with '0F000D' and some bits cycling under the icon indicating it is performing a memory test.

This numeric code is in two parts:

- The first two characters are the class code. The class code tells what part of the diagnostic program found the error.
- The second four are the sub code. The sub class code tells what the error was. In the case of a bad RAM chip, the sub class identifies the bad chip (this was very helpful to homegrown upgraders).

Class Code	Sub Code
1=ROM test failed	Meaningless
2=Memory test--bus subtest	identifies bad chips
3=Memory test--byte write	identifies bad chips
4=Memory test--Mod3 test	identifies bad chips
5=Memory test--address uniqueness	identifies bad chips

Single Chip Identification		
Data Bit	**Location**	**Sub Code Bits**
0	F5	0001
1	F6	0002
2	F7	0004
3	F8	0008
4	F9	0010
5	F10	0020
6	F11	0040
7	F12	0080
8	G5	0100
9	G6	0200
10	G7	0400

11	G8	0800
12	G9	1000
13	G10	2000
14	G11	4000
15	G12	8000

Class Code	Sub Code	Sub Code Meaning
F=Exception	0001	Bus error
	0002	Address error
	0003	Illegal Instruction
	0004	Zero divide
	0005	Check instruction
	0006	Traps instruction
	0007	Privilege violation
	0008	Trace
	0009	Line 1010
	000A	Line 1111
	000B	Other exception
	000C	Nothing
	000D	NMI (normal indication)
	0064	Couldn't read System File into memory

Macintosh SE and Macintosh II ROMs

The "sad Macintosh" error codes for Macintosh SE and Macintosh II computers were changed to incorporate additional power for testing and to support the 32-bit world. Generally, the same codes are used for 68000 exceptions as the Macintosh but they are displayed differently.

Traditional

The traditional Macintosh error codes are displayed in hexadecimal notation like this: 0F0003

Where F indicates an exception occurred, and 3 indicates an illegal instruction occurred. On the Macintosh SE and Macintosh II, the display would appear:

0000000F
00000003

Power On

The power-on error codes have the following format:

XXXXYYYY
ZZZZZZZZ

Where XXXX is internal test manager state information (ignore this), YYYY contains codes that indicate either an exception code, or the test number for a power on test failure. The *ZZZZZZZZ* code contains additional failure information to help track down the fault.

YYYY Error Codes	
Error Code	**Meaning**
$0001	The ROM checksum test failed. Ignore the Z field.

$0002	The first small chunk of RAM to be tested failed. The Z field indicates which RAM Bit(s) failed. This small chunk of RAM is always in Bank B. Using $AABBCCDD as a guide: AA=8 bit mask for bits 31-24 BB=8 bit mask for bits 23-16 CC=8 bit mask for bits 15-8 DD=8 bit mask for bits 7-0
$0003	The RAM test failed while testing bank B, after passing the chunk tested for code $0002. The Z field indicates which bits failed as in code $0002.
$0004	The RAM test failed while testing bank A. The Z field indicates which bits failed as in code $0002.
$0005	The RAM External addressing test failed. The Z field indicates a failed address line.
$0006	Unable to properly address the VIA1 chip. The Z field is not applicable.
$0007	Unable to properly address the VIA2 chip (Macintosh II only). The Z field is not applicable.
$0008	Unable to properly access the Front Desk Bus. The Z field is not applicable.
$0009	Unable to properly access the MMU. The Z field is not applicable.
$000A	Unable to properly access NuBus. The Z field is not applicable.
$000B	Unable to properly access the SCSI Chip. The Z field is not applicable.
$000C	Unable to properly access the IWM chip. The Z field is not applicable.
$000D	Unable to properly access the SCC Chip. The Z field is not applicable.
$000E	Failed Data Bus test. The Z field indicated the bad bit(s) as a 32-bit mask for bits 0-31. This may indicate either a bad SIMM or data bus failure.
$000F	Reserved for Macintosh compatibility.
$FFxx	A 680xx exception occurred during power on testing. The xx indicates the exception: $01 Bus Error $02 Address Error $03 Illegal Instruction Error $04 Zero Divide $05 Check Instruction $06 cpTrapCC, Trap CC, Trap V $07 Privilege violation $08 Trace $09 Line A $0A Line F $0B unassigned $0C CP protocol violation $0D Format exception $0E Spurious interrupt $0F Trap 015 exception $10 Interrupt Level 1 $11 Interrupt Level 2 $12 Interrupt Level 3 $13 Interrupt Level 4 $14 Interrupt Level 5 $15 Interrupt Level 6 $16 Interrupt Level 7 $17 FPCP bra or set on unordered condition $18 FPCP inexact result $19 FPCP divide by zero $1A FPCP underflow $1B FPCP operand error $1C FPCP overflow $1D FPCP signalling NAN $1E PMMU configuration $1F PMMU illegal operation $20 PMMU access level violation

Macintosh Portable ROMs

The startup code in the Macintosh Portable contains a series of startup tests that are run to ensure that the fundamental operations of the computer are working properly. If any of those tests fail, a "sad Macintosh" icon appears on the screen with a code below that describes what failure occurred. Here is a typical example of a Sad Mac display with an error code below it:

SAD MAC CODE

05460203 = (D7.L)
000OB6DB = (D6.L)

The two codes are actually the contents of the two CPU data registers D6 and D7. The upper word (upper 4 hexadecimal digits, in this case 0546) of D7 contains miscellaneous flags that are used by the start-up test routines and are unimportant to just about everybody except a few test engineers within Apple. The lower word of D7 is the major error code. The major error code identifies the general area the test routines were in when a failure occurred. D6 is the minor error and usually contains additional information about the failure, something like a failed bit mask.

SAD MAC CODE BROKEN DOWN

Test Flags Major Error

0546 0203

Minor Error Minor Error

0000 B6DB

The major error is further broken into the upper byte that contains the number of any 68000 exception that occurred ($00 meaning that no exception occurred), and the lower byte that usually contains the test that was being run at the time of failure. If an unexpected exception occurred during a particular test, then the exception number is logically ORed into the major error code. This way both the exception that occurred as well as the test that was running can be decoded from the major error code:

SAD MAC CODE FURTHER BROKEN DOWN

68000 Exception Test Code

02 03

In this example, the code says that an address error exception ($0200) occurred during the RAM test for Bank A ($03); $0200 ORed with $03 = $0203.

Major Error Codes

Below is a brief description of the various test codes that might appear in the major error code:

Important: Some of these codes may mean slightly different things in Macintosh models other than the Macintosh Portable. These descriptions describe specifically how they are used in the Macintosh Portable.

Major Error Codes	
Error Code	**Meaning**
$01	ROM test failed. Minor error code is $FFFF, which means nothing.
$02	RAM test failed. Minor error code indicates which RAM bits failed.
$05	RAM external addressing test failed. Minor error code indicates a failed address line.
$06	Unable to properly access the VIA 1 chip during VIA initialization. Minor error code not applicable.
$08	Data bus test at location eight bytes off of top of memory failed. Minor error code indicates the bad bits as a 16bit mask for bits1500. This may indicate either a bad RAM chip or data bus failure.
$0B	Unable to properly access the SCSI chip. Minor error code not applicable.
$0C	Unable to properly access the IWM (or SWIM) chip. Minor error code not applicable.
$0D	Not applicable to Macintosh Portable. Unable to properly access the SCC chip. Minor error code not applicable.
$0E	Data bus test at location $0 failed. Minor error code indicates the bad bits as a 16bit mask for bits 1500. This may indicate either a bad RAM chip or data bus failure.
$10	Video RAM test failed. Minor error code indicates which RAM bits failed.

$11	Video RAM addressing test failed. Minor error code contains the following: upper word = failed address (16-bit) msb of lower word = data written lsb of lower word = data read Data value written also indicates which address line is being actively tested.
$12	Deleted
$13	Deleted
$14	Power Manager processor was unable to turn on all the power to the board. This may have been due to a communication error with the Power Manager. If so, the minor error code contains a Power Manager error code, explained in the next section.
$15	Power Manager failed its self-test. Minor error code contains the following: msw = error status of transmission to power manager. lsw = Power Manager self-test results (0 means it passed, non-zero means it failed)
$16	A failure occurred while trying to size and configure the RAM. Minor error code not applicable.

Minor Error Codes; Power Manager Processor Failures

If a communication breakdown occurs during communication with the Power Manager, the following error codes appear somewhere in the minor error code (usually in the lower half of the code, but not always):

Minor Error Codes	
Error Code	**Meaning**
$CD38	Power Manager was never ready to start handshake.
$CD37	Timed out waiting for reply to initial handshake.
$CD36	During a send, Power Manager did not start a handshake.
$CD35	During a send, Power Manager did not finish a handshake.
$CD34	During a receive, Power Manager did not start a handshake.
$CD33	During a receive, Power Manager did not finish a handshake.

Diagnostic Code Summary

Below is a summarized version of the Sad Mac error codes:

Diagnostic Code Summary	
Test Codes	**Meaning**
$01	ROM checksum test.
$02	RAM test.
$05	RAM addressing test.
$06	VIA 1 chip access.
$08	Data bus test at top of memory.
$0B	SCSI chip access.
$0C	IWM (or SWIM) chip access.
$0D	No applicable to Macintosh Portable; SCC chip access.
$0E	Data bus test at location $0.
$10	Video RAM test.
$11	Video RAM addressing test.
$14	Power Manager board power on.
$15	Power Manager self-test.
$16	RAM sizing.

Power Manager Communication Error Codes	
Error Code	**Meaning**
$CD38	Initial handshake.
$CD37	No reply to initial handshake.
$CD36	During send, no start of a handshake.
$CD35	During a send, no finish of a handshake.
$CD34	During a receive, no start of a handshake.
$CD33	During a receive, no finish of a handshake.

CPU Exception Codes (as used by the startup tests)	
Error Code	**Meaning**
$0100	Bus error exception code.
$0200	Address error exception code.
$0300	Illegal error exception code.
$0400	Zero divide error exception code.
$0500	Check inst error exception code.
$0600	cpTrapcc,Trapcc,TrapV exception code.
$0700	Privilege violation exception code.
$0800	Trace exception code.
$0900	Line A exception code.
$0A00	Line F exception code.
$0B00	Unassigned exception code.
$0C00	CP protocol violation.
$0D00	Format exception.
$0E00	Spurious interrupt exception code.
$0F00	Trap inst exception code.
$1000	Interrupt level 1.
$1100	Interrupt level 2.
$1200	Interrupt level 3.
$1300	Interrupt level 4.
$1400	Interrupt level 5.
$1500	Interrupt level 6.
$1600	Interrupt level 7.

Apple High-Resolution Monitors: Using with Overhead Projectors

The barely visible, thin horizontal lines present on most Apple High-Resolution Monitor screens are causing problems for my LCD overhead projector. Are there any ways to reduce these practically invisible lines?

This article has been archived and is no longer updated by Apple.
The horizontal line you're talking about is the Color Grid Stabilizing Wire; removing or altering it in any way would make your monitor much more fuzzy. Most overhead projectors don't go through the monitor, so the stabilizing wire shouldn't be a factor. If your projector does go through the monitor, you may want to replace it with one that connects directly to a video interface card instead.

Check the Redgate Buyer's Guide library here on AppleLink for possible sources.

Macintosh: Generic Pinouts for 9600 Baud V.32/V.42 Modems

What are the generic pinouts for connecting a Macintosh to a high-speed 9600 baud V.32/V.42 modem?

This article has been archived and is no longer updated by Apple.

Here are the generic pinouts:

Modem	Macintosh
1-7	4-8
2	3
3	5
5	2
4	1

These pinouts apply to all "V" series modems and all Macintosh computers. Older Macintosh computers have slightly different serial ports than the later machines and may not support the fastest possible Macintosh-to-modem speeds.

Macintosh: Third-Party Hard Disk Partitioning

Can I create 10 or more partitions on a third-party 600MB hard drive and have them all available on the Macintosh desktop at the same time?

This article has been archived and is no longer updated by Apple.

Since you have a third-party drive, you'll need to use a third-party hard disk utility. This utility should be provided by the manufacturer of the drive. If not, a program called SilverLining from La Cie works well.

TA46383_Macintosh_MacPaint_Fill_(TIL00776).pdf

Macintosh MacPaint: Fill

This article has been archived and is no longer updated by Apple.
Normally the MacPaint bucket allows for a single filling of a bounded area of a shape. If you wish to try various fills to see which looks best, select Undo on the Edit Menu after each fill.

The May 1984 Version 1.3 of MacPaint has a new Fill command on the Edit Menu. To use it, lasso an object and select Fill. The active fill pattern at the bottom of the palette will fill the entire object. There are no limitations on the number of times an object may be filled. The bucket still has its original limitations.

Often there is the need to put one outline shape on top of another and to have both shapes filled with the same pattern. This helps you to position objects and text, providing a "stop" every eight fatbits. The smallest square that may be created while the grid is active is nine by nine fatbits. Unlike the grid in LisaDraw, this grid is invisible and nonadjustable.

TA46385_Macintosh_Portable_Modifying_for_Use_by_the_Handicapped_(TIL07764).pdf

Macintosh Portable: Modifying for Use by the Handicapped

Can the Macintosh Portable's display screen be detached? A customer wants to detach the display and mount it on a swing arm of a wheelchair, with the rest of the Portable under the wheelchair.

Is this possible?

This article has been archived and is no longer updated by Apple.
It is possible to remove the screen from the Macintosh Portable, but you'll need a special monitor extension cable that Apple does not manufacture.

Also, Aura Systems makes a product called ScuzzyGraph that allows connection of monochrome and color monitors to the Macintosh Portable and other members of the Macintosh family.

To locate a vendor's address and phone numbers, use the vendor name as a search string.

Macintosh: Mysterious Bombs May Be SCSI or RAM

I have a problem with my Macintosh bombing frequently at startup. My system also bombs at other times, such as when booting or quitting a program, but generally, most bombs occur at startup.

When opening DBase Mac, I get a message that the program has been corrupted. Open the program again and it runs fine. I get a variety of system errors such as ID-04, ID-01 and ID-25.

QuarkXPress 2.12 freezes on the screen while opening, yet an exact copy of QuarkXPress will install and run just fine on another Macintosh. Also, PageMaker 4.0 bombs when trying to "Place" a document or a graphic, as does Excel 2.2 when opening or closing.

I am using all standard Apple equipment, including an 80MB Quantum hard drive with a corrected EPROM and 5MB of RAM.

I have installed System 6.0.5 from the original Installer disks and have removed all INITs.

I have run Macintosh SE/30 diagnostics on the computer and Apple HD diagnostics on the hard drive--and all tests pass.

This article has been archived and is no longer updated by Apple.
Even though your system has passed its diagnostics, you could still be experiencing a RAM or SCSI problem.

RAM problems can show up after warm-up. For example, a marginal SIMM's speed may be fine when cool but slow down after warming up. All SIMMs do this to a certain extent, but you may have a SIMM that crosses the Macintosh SE/30's tolerance threshold when warm. The only fix for this is to replace the offending SIMM or SIMMs. A similar problem could be happening within the memory manager's circuitry on the logic board, the only possible fix being a complete logic board replacement.

More likely, this is a SCSI problem, particularly if you have external SCSI devices attached. We have seen this problem most often when there are external SCSI devices attached but not turned on. All SCSI devices must be powered on before starting the Macintosh and they must be left on until the Macintosh is turned off. Doing otherwise can introduce garbage onto the SCSI data line. Improper termination of the SCSI chain will also cause this problem.

If your SCSI chain is found to be the source of your problem, be aware that your hard drive's format may be corrupted (the garbage on the SCSI chain having corrupted the format). You'll need to reformat your hard drive with either all the external SCSI devices removed or powered on.

Macintosh: Cut from MacWrite and Paste to MicroSoft BASIC

Can I turn MacWrite files into MS-BASIC code?

This article has been archived and is no longer updated by Apple.

MacWrite files of MS-BASIC code can be turned into a program.

1. Leave MacWrite and open a new MS-BASIC document.
2. Type the MERGE command with the syntax, MERGE "volumename:filename", where
   "volumename" is the name shown under the disk's icon on the desktop and
   "filename" is the name you gave your MacWrite file.

See page 119 of the MS-BASIC manual for information about MERGE.

Note that if you stored text in more than one MacWrite document, you should repeat the command until you have MERGED the remainder of your files into the new BASIC program. The program will be named with the name of the last file you merged into it.

Apple Scanner: Using with a Macintosh IIfx

Article Change History

12/22/92 - UPDATED
* To include Scanner driver 2.0 information.

Is there any trick for getting an Apple Scanner to work with a Macintosh IIfx? I keep getting a "scanner not found" message. The Macintosh IIfx terminator is installed in the scanner's second SCSI port.

Do I need a second terminator when using with a Macintosh IIfx? Does it need to be an fx-type?

This article has been archived and is no longer updated by Apple.
The Macintosh IIfx is very picky about its termination. At no time should there be more than two terminators in the entire SCSI chain -- one on each end, or in the case of only one internal SCSI hard drive, a single terminator installed internally. All terminators used with the Macintosh IIfx must either true IIfx-compatible or "augmented" by the IIfx SCSI Filter (used only with internal hard drives).

In addition, older Apple Scanners had some additional capacitors installed on the logic board, which may garble the SCSI signals when connected to faster Macintosh computers. Install the Scanner driver version 2.0 to correct this problem.

AppleShare: Requires Dedicated Server

If I had enough RAM, would it be possible to run AppleShare file and print servers on my Macintosh in the background under MultiFinder? I know that the instructions state that I need a dedicated machine, but I only need to use a few other programs.

This article has been archived and is no longer updated by Apple.
Unfortunately, there is no way to make either the AppleShare File Server or Print Server run in the background under MultiFinder The "administrative" portions of these systems can run concurrently under the server software, but that is not the same as running in the background The actual code that drives the server software actually modifies the operation of the System to such an extent that most applications would be incompatible with it.

Apple IIGS: How To Make a GS/OS 5.0.2 Diskette

I am tying to get my Apple IIGS to print AppleWorks 3.0 files on a LaserWriter over LocalTalk or local ImageWriter.

I started out with an AppleWorks 2.0 disk that worked just fine on my Apple IIGS (ROM v1.0). I copied the disk, then replaced my AppleWorks 2.0 files with AppleWorks 3.0 files. When I chose Chooser, the Apple IIGS went into what looked like machine language or Pascal code. ▌then tried using the old AppleWorks 2.0 disk and it did the same thing. I tried to configure a AppleWorks 3.0 disk with GS/OS 5.02 but I can't figure out what files are necessary to do this. ?

This article has been archived and is no longer updated by Apple.

Your problems are caused by the setup differences between GS/OS 4.0 and 5.0.2. Here are the steps to make a bootable GS/OS 5.0.2 diskette that can print to a LaserWriter and/or ImageWriter:

1) Boot GS/OS 5.0.2; format a blank 800K diskette and called it "Startup".

2) Run the Installer program from the SYSTEM.TOOLS diskette, and install the option "AppleShare on 3.5" onto the Startup diskette.

3) Still within Installer, "Remove" the option called "AppleShare" from the Startup diskette.

4) Using Installer, install the LaserWriter and LocalTalk ImageWriter options onto the Startup diskette.

Hint: try to have two 3.5" drives--if you don't it may take you up to one hour to do the above with only one floppy drive.

This will get you a bootable diskette that contains the absolute minimum operating system and the necessary printer drivers. From a hardware standpoint, make sure that slot 1 in the Apple IIGS control panel is set to "AppleTalk" and that you set AppleWorks to print to slot 1 -- the older Apple IIGS had a different control panel setting.

Note: you may not be able to fit both the operating system and AppleWorks onto a single diskette.

AppleShare Print Server: Printing Too Many Copies Problem

Every time we send 15 or more pages to the AppleShare Print Spooler, the server automatically doubles or triples the total number of pages printed.

This problem happens no matter what kind of Macintosh we're using or what kind of document we are printing.

This article has been archived and is no longer updated by Apple.
This problem is most likely occurring because the AppleShare Print Server is losing AppleTalk signal packets. In the middle of a print job, the server can sometimes "lose" its connection with the LaserWriter. When this happens, the server automatically resends the entire print job.

There are a couple of things you can do to alleviate this problem. First, be sure you're using at least LaserWriter driver 6.0.1. This version has optimized "answer-back" code for the LaserWriter that continually says "I'm here" to the print server during printing (which is what tells the server to maintain its connection). If your LaserWriter isn't doing that often enough you'll lose the connection.

Next, check for any devices that may be causing an excessive amount of network noise. The most time-consuming (but most reliable) way to do this is to make your network as small as possible (two or three devices). Then test for noise, adding devices until the problem is found. Using a network utility like Inter*Poll can help locate noisy devices. If you're using any routers in your network, try disconnecting them--the extra time required to route data packets may be contributing to the problem.

AppleWorks: Third Party Printers Form Feed Issue

This article discusses a form feed issue with some third party printers.
This article has been archived and is no longer updated by Apple.
At times, AppleWorks' Top-of-Form command does not work properly with some third party printers, including the Juki printer. If your printer seems to ignore AppleWorks' Top-of-Form command, follow this procedure:

1. Check the printer's Top-of-Page and Lines-Per-Inch settings.
2. Change AppleWorks' "Accepts Top of Page" to NO.
3. Turn off the printer.
4. Align the top of the form on the printer.
5. Turn on printer.
6. Proceed as usual.

Macintosh: Troubleshooting a "System Error ID=01" Message

My setup is a:

- Macintosh IIci; 80MB hard disk; 8MB RAM
- Radius TP color display
- Scanner
- External HD
- Tape Backup
- System Software 6.0.4

When I attempt to start up from the internal hard disk, a "System Error ID=01" message appears and the system will not start up. The system will start up from a disk copy of the System. Reinstalling the System to the internal HD has not worked.

This article has been archived and is no longer updated by Apple.
ID=01 is a bus error.

First, use Find File or a similar tool to verify that there is only one System file on the hard drive. Next, remove all non-Apple files from the System folder and restart. If this does not fix the problem, you may have a hardware problem. Try a different hard drive first, and then try a different logic board.

The other thing that could be causing the problem is the video card for your Radius display. Try replacing the Radius with an Apple video card and monitor.

Macintosh IIfx Terminators: Compatible with Macintosh Family

Can the special external terminator supplied with the Macintosh IIfx be used on other Macintosh computer SCSI chains?

This article has been archived and is no longer updated by Apple.

Yes, you can use the new black terminators on other Macintosh SCSI devices.

Published Date: Feb 18, 2012

Apple IIGS: Troubleshooting SCSI Problems

My Apple IIGS, with a High Speed SCSI Card installed, gets an error code #8002 when copying between SCSI hard drives. What does this error code mean?

This article has been archived and is no longer updated by Apple.
Error code #8002 isn't part of the generic GS/OS 5.0.2 operating system. This suggests the error code is coming from the SCSI driver.

Most problems with the High Speed SCSI card come from improper installation of the SCSI drivers. Specifically, people often don't install the new drivers that come with the card using the original GS/OS SCSI drivers instead.

Here are some troubleshooting steps to try:

1) Create a new boot diskette that contains GS/OS 5.0.2 and the new SCSI drivers (the drivers are installed via the Installer program located on the High Speed SCSI Card Utility diskette).

2) Try to copy between SCSI devices after booting with this diskette.

3) If you can copy successfully, then reinstall the GS/OS onto your hard drive. Remember to reinstall the new SCSI drivers before rebooting from the hard drive.

Depending on the current state of the operating system already on the hard drive, you may have to trash the existing System and Icons folder.

Why the Macintosh Has No Parity Checking

This article has been archived and is no longer updated by Apple.

Here's why Macintosh systems don't implement parity checking:

- Reliability. RAM is typically the most reliable component in our systems.

- Simplicity. Parity checking requires additional hardware overhead, which lowers reliability.

- Low chip count. The systems for which parity checking was originally designed required more chips for the same amount of RAM. RAM chips used in these older system were far less reliable than the chips used today.

- The Macintosh does a full read/write RAM test every time it is switched on. This test is a sufficient diagnostic.

LaserWriter: Sharing Access Over Ethernet

I have an AppleShare network running over Ethernet. Can I share my LaserWriter IINT with everyone else on the network if it's connected to one of the workstations rather than the server?

This article has been archived and is no longer updated by Apple.
Since the LaserWriter is a LocalTalk device, you can put it anywhere in the loop. But you will need to have some kind of router installed on the network to change the LocalTalk protocols to Ethernet protocols.

There are a couple of ways to do this:

* With a hardware router, such as the Kinetics Fastpath. This device would actually be a separate node on the network.

* With the Apple Internet Router. This is software that is installed on a single Macintosh that can connect to both types of networks. In your case, the most logical place to put it would be on the server, but that is not a strict requirement. The router runs in the background, but if you install it on a workstation, and that machine somehow is turned off (in a system crash, for example) then everyone will lose access to the LaserWriter.

For more information, search on "ROUTER AND ETHERNET"

Published Date: Feb 18, 2012

LaserWriter Plus: Running Out of Memory Problem

On my LaserWriter Plus, I'm printing a lot of non-LaserWriter fonts and graphics. I often get the error message that printing exceeds printer memory. How can I fix this?

This article has been archived and is no longer updated by Apple.
The LaserWriter Plus comes with 1.5MB of RAM. Since the LaserWriter Plus cannot be expanded with more on-board RAM, your only recourse is to purchase (or upgrade) to a higher-end LaserWriter. The LaserWriter IINT has 2MB of RAM, and the LaserWriter IINTX has up to 12MB of RAM.

TA46406_Personal_LaserWriter_Using_Overseas_(TIL07796).pdf

Personal LaserWriter: Using Overseas

Is a step-down transformer required for using a Personal LaserWriter overseas? It appears that it does because on the back of the printer it states 100-115v at 50-60 Hertz. Also, why does the printer specification sheet give both US/Japan and European/Australian power requirements?

This article has been archived and is no longer updated by Apple.
As with our other LaserWriter printers, there are voltage-specific versions available. There are actually two different Personal LaserWriters versions: one for the US/Japan market and the other for the European/Australian market.

You do need a step-down transformer if you take a Personal LaserWriter overseas, just as you would for any LaserWriter or LaserWriter II.

Published Date: Feb 18, 2012

PrintMonitor: Troubleshooting "Quit Unexpectedly (3)"

When printing to a LaserWriter in MultiFinder with Background Printing on, the PrintMonitor will either "Quit Unexpectedly(3)" or just not print.

The files I'm trying to print remain in the Spool Folder with the PrintMonitor appearing every 10 seconds to announce that it has "Quit Unexpectedly(3)". This keeps happening until PrintMonitor is removed from the System folder or the spool files are removed from the Spool folder.

Also, the PrintMonitor "Quits Unexpectedly(3)" when I double click on it.
This article has been archived and is no longer updated by Apple.
Note: This issue is System 6 specific.

Most often, applications unexpectedly quit because they ask for more memory than has been allocated to them, the Memory Manager says "no", and the application has no idea what to do next.

PrintMonitor, even though it looks like a standalone application, does not use the RAM allocated to it during the background printing process. Instead, PrintMonitor uses some of the RAM allocated to the Finder. If the Finder (in the background) is maintaining a lot of items, such as open windows, mounted file server volumes, and so on, there may not be enough RAM left over for PrintMonitor to work. Try allocating more memory to Finder, such as 320K (the default is 160K).

Another possible problem is a corrupted Backgrounder file, the INIT that handles the background task management. Since PrintMonitor is appearing periodically to check the Spool Folder, it's probable that Backgrounder is fine and you're seeing only a memory limitation.

And finally, there may be an INIT that is conflicting with PrintMonitor's operation. Removing all non-essential INITs and testing will tell you if that's the problem.

AppleShare Print Server: Capture and Release Questions

I have some questions on AppleShare Print Server:

A) If a printer is "captured" for print service, can another user, who is not set up with the "captured" LaserWriter spooler in the Chooser, print to that printer directly or is that printer unavailable?

B) It is not clear to me from reading the manual if the captured printer is always releaseable. What are the parameters for releasing a printer?

C) We currently have five LaserWriters that we plan to capture for print service. In the next two months we plan to add two more printers. How will we be able to capture those printers for service on the network? Will we have to buy another AppleShare Print Server? If so, can we run two print servers on the same file server? How is this best accomplished?

This article has been archived and is no longer updated by Apple.
Here are the answers to your A) If you select Printing, Spooling, and Bypass in the Options dialog box, the captured printer can be printed or spooled to directly. Both options will be available to all users in their Choosers.

B) A captured printer can always be released. To release a printer from the spooler:
1. choose Setup from the File menu
Printer Types box
3. select the particular printer you want to release
4. click the Release button.

C) The AppleShare print server can capture from one to five printers, depending on the amount of RAM available to the print server application. To capture more than 5 printers you will need a second print server system.

Super Serial Card: Using Serial Multiplexer (12/96)

This article discusses using the Super Serial Card with a Serial Multiplexer.

This article has been archived and is no longer updated by Apple.

To reduce costs, many schools install a Serial Multiplexer to allow many Apples to share an Imagewriter. The multiplexer scans each computer by sampling a signal called "Data Set Ready" or DSR from the Super Serial Card in each IIe.

The nature of the SSC causes a modem nullifier to map this signal to DTR, "Data Terminal Ready." Normally this signal is not turned off by the computer since other equipment, like a modem, requires this signal to remain on. In this configuration the Serial Multiplexer stops scanning and hangs if the signal is not dropped. A simple POKE in BASIC releases the line.

The general form is: POKE 49050+256*Slot,1

Example

Most systems have the SSC in slot 1, so the command is:

POKE 49306,0

Macintosh Scrapbook: Copying Between Different Computers

I want to put the Scrapbook file from one Macintosh in the System folder of another Macintosh. Will this cause any problems?

This article has been archived and is no longer updated by Apple.
We don't see any problems copying the Scrapbook between Macintoshes. The only time when there may be a problem is when the one computer is using a much older version of the System software. Then you will need to copy the contents of the clipboard out or update the older version of the System software.

Apple II Plus: Relocation/Configuration Error (2/97)

What is the meaning of a relocation/configuration error on the Apple II Plus when running ProDOS?

This article has been archived and is no longer updated by Apple.

ProDOS requires 64K of RAM to run. The error you are getting means that you have only 48K of RAM.

SCSI: Using SCSI ID Address #0

Can you clarify an issue concerning SCSI addresses? The Macintosh is always address #7. Internal hard drives are always address #0. For a Macintosh that doesn't have an internal hard drive, can its external drive use address #0? Is #0 reserved by the system? Is there some special significance associated with the #0 address?

This article has been archived and is no longer updated by Apple.

The SCSI address #0 is a special address, but it is not absolutely reserved for system use. Not taking the Startup Device cDEV into account, if the Macintosh sees a storage device attached to it that has a SCSI ID of 0, then it will wait for that device to come up to speed to see if it is bootable. If it is bootable, the system will start up from that device. There is no other special significance attached to the #0 ID, so you can set an external device to it if you like.

Apple Tape Backup: Recovering Lost Data

I backed up my system using Apple Tape Backup then accidentally backed up another smaller system on the same tape. Is there any way to recover the remaining data from the first backup?

This article has been archived and is no longer updated by Apple.
Since the volume information of the tape is stored at the beginning of the tape, the original contents of the tape would have been lost when a new directory was written on the tape. Something you might try is to use the INIT Tape Disk that comes with the Tape Backup 40SC software. Mount the cartridge as a streaming device on the desktop, then attempt to use a recovery utility, such as SUM, to recover the lost files.

Apple Internet Router: One Zone Per LocalTalk Port

The beta version of the Internet Router supported four zones on two physical LocalTalk ports. According the documentation for the Internet Router version 2.0, and from several articles in the AppleLink Technical Info Library, it appears that one zone per physical LocalTalk Port is the new limit. Is this correct? If so, are there any solutions or workarounds?

This article has been archived and is no longer updated by Apple.
Yes, that function was not implemented in the released version of the Apple Internet Router. To our knowledge the only way you can have more zones than physical ports is to add another interface card with a port on it.

HyperCard: Hanging Up The Phone

When you use HyperCard's dial command with a modem, HyperCard doesn't hang up the phone right away if the line is busy. This is because the dial command simply sends a string to the modem and doesn't check whether the line is busy.
This article has been archived and is no longer updated by Apple.
You can create a button that hangs up the modem. The basic format of the dial command is:

dial phonenumber with modem modemCommands

If you specify 'with modem,' HyperCard sends the information out the modem port. The modemCommands are commands you can send to the modem, such as the Hayes command set with which Apple modems are compatible.

To tell HyperCard to dial the number

9,555-1212

you'd use the dial command

dial "9,555-1212" with modem "ATS0=0DT"

which would send the string ATS0=0DT9,555-1212 out the modem port. If your modem understands the Hayes command set, it dials the phone. Because Hypercard is not looking at the modem port, it ignores any "busy" signal sent by the modem.

To make the modem hang up, you need a button that sends a character to the modem. This button script hangs up the phone if it gets a busy signal:

```
on MouseUp
dial "n" with modem " "
-- n can be any number. The space in quotes is there because the
-- default for the 'with modem' command is ATS0=0DT.
end MouseUp
```

LaserWriter: Shrinking Image Problem

I have a LaserWriter Plus that shrinks any image that I print. After I replaced the scanner, the problem went away for a while. Now the shrinking problem is back again. I'm curious as to whether the problem was caused by just the scanner or something else.

This article has been archived and is no longer updated by Apple.
It may be that either the motor, the DC Power Supply/motor driver PCB, or the DC Controller is causing this problem. On more than one occasion the power supply has been the culprit.

Macintosh: SIMM Thickness Tolerances

What are the upper and lower limits for Macintosh SIMMs? I know the official size is 1.27mm, but how much tolerance is there?
This article has been archived and is no longer updated by Apple.
The 1.27mm thickness is Apple's specification. Thicker SIMM PCBs can bend the retaining springs out. This isn't a problem as long as thinner SIMMs are never inserted into the same sockets.

If thinner than 1.27mm SIMMs are used, the chance increases of having weak or impaired connections.

The main point to remember is that Apple's sockets are for 1.27mm SIMMs. If you buy SIMMs from Apple, you can be sure they're OK. If you buy from a third party, be sure to ask for SIMMs with the right thickness.

ImageWriter II: Troubleshooting Garbled Printing

The printing on my ImageWriter II has become garbled garbage. It's missing the page breaks and prints onto other pages. This happens after about 6 or 7 pages have printed. I've tried cleaning the platen and replacing main circuit board.

This article has been archived and is no longer updated by Apple.

This sounds like a handshake problem in communication between the computer and the printer. It could be caused by a number of glitches, among them a bad driver, bad cable, or printing software.

Try to recreate the problem using:

- a different computer with the same application and file
- a different printer
- a different printer cable

Published Date: Feb 18, 2012

Macintosh Memory Allocation: "Application Has Unexpectedly Quit"

I keep getting out of memory error messages when performing tasks in an application. I also get "Application has unexpectedly quit" error messages.
This article has been archived and is no longer updated by Apple.
This kind of error is usually caused by an application, INIT (Extension), or CDEV trying to grab more memory than it has been allocated.

Here are some fixes, depending on what's causing the problem:

* Allocate more memory to the application. Under System 6 Finder, applications could grab a lot more memory. Some manufacturers don't set the partition high enough to do certain operations in their programs. To increase the RAM allocation, change the "Application Memory Size" box in the Get Info dialog box for the application.

* Replace the application with a new copy. It may be that the application is corrupted.

* Allocate more memory to PrintMonitor. If you're seeing the error most often when printing, and you have background printing turned, try allocating more RAM to PrintMonitor first. Then increase RAM for the application.

* Reduce the number of INITs (Extensions) and CDEVs running on the system. Remove all INITs (Extensions) that aren't a fundamental part of the system software or application. Some INITs use a large amount of memory.

* Try reinstalling the system software. Damaged or corrupted system files can cause this error as well.

* If running System 6, an alternate (unsupported) solution is to increase the amount of RAM allocated to the system heap using CE Software's HeapFixer.

Note: Altering the system heap can cause other, more unpredictable errors. Also note that if running System 7, the system heap is adjusted dynamically, and HeapFixer isn't necessary.

For more information, contact CE Software. (To locate a vendor's address and phone numbers, use the vendor name as a search string.)

* This would also be a good time to check for viruses. They can contribute to unusual system behavior.

Macintosh LC: VRAM Memory Map Correction

The memory map in the "Macintosh LC Computer Developer Note" shows the VRAM space as $FC 0000-$FF FFFF. This gives 256K of memory. How does the 512K VRAM SIMM map into this smaller area?

This article has been archived and is no longer updated by Apple.
The "Macintosh LC Computer Developer Note" is wrong.

The memory spaced used by VRAM is in the following ranges:

24-bit mode	32-bit mode
$F4 0000 to $FB FFFF	$50F4 0000 to $50FB FFFF

With the 512K VRAM SIMM installed, the entire range from $F4 0000 to $FB FFFF (24-bit mode) or $50F4 0000 to $50FB FFFF (32-bit mode) is used. ($FB FFFF minus $F4 0000 is $07 FFFF, which equals 512K.)

With the 256K VRAM SIMM installed, the range from $F4 0000 to $F7 FFFF (24-bit mode) or $50F4 0000 to $50F7 FFFF (32-bit mode) is used; $FB FFFF minus $F7 0000 is $03 FFFF, which equals 128K.

Note: The range from $F8 0000 to $FB FFFF (24-bit mode) or $50F8 0000 to $50FB FFFF (32-bit mode) maps to the range from $F4 0000 to $F7 FFFF (24-bit mode) or $50F4 0000 to $50F7 FFFF (32-bit mode). In other words, if a change is made to $F8 0000, the same change will be made to $F4 0000. The reverse holds true as well: a change to $F4 0000 will reflect in $F8 0000.

Macintosh: Double lines in MacWrite

This article has been archived and is no longer updated by Apple.

Double lines, which are often used to set off a heading or divide segments in a bulletin, can easily be created in MacWrite. To do so: hold down the command key while pressing the letter U to toggle on the underline operation, or choose Underline from the Style menu. Next, hold down the Shift key while pressing the hyphen/line key (to the left of the = key); you should see a double line move across the screen.

Creating the same effect under a word or a group of figures in a column can only be approximated. First, enter the double line for two or three spaces. Then enter your figures with the Underline option toggle on to get a single underline, and then follow with a double line for two or three more spaces.

This suggestion was reprinted from the Open Window column in the December 1984 issue of MacWorld.

LaserWriter IINT: Possible Reasons for Slow Printing

I'm trying to print a MORE document with a SuperPaint picture. The last page of the document prints fine on a LaserWriter, but takes a long time on a LaserWriter IINT.

Is there a problem with the LaserWriter IINT?

This article has been archived and is no longer updated by Apple.
There are several possible causes for slow printing on a LaserWriter IINT:

* There are too many fonts downloaded to the LaserWriter IINT's memory.

* There is an Apple II printing to the LaserWriter IINT. An Apple II slows down the LaserWriter IINT by downloading an ImageWriter emulator.

* There is a network problem causing the LaserWriter IINT to retry. Use Inter*Poll and send several thousand packets to the printer to see how many packets come back with errors. Too many errors suggests a bad cable or printer I/O board.

Macintosh: Meaning of the Desktop DB & Desktop DF Files

Why do I have these files on my Macintosh?:

Desktop DB
* Desktop DF
This article has been archived and is no longer updated by Apple.
The Desktop DB/Desktop DF files are invisible files that are not normally seen by users. The files were original created by the Desktop Manager of AppleShare 2.0 running under System 6.0.x to maintain information in addition to the Finder's Desktop file at that time. There were designed to be more high performance databases to support faster access to information for AppleShare servers.

Under System 7, functions of the Desktop Manager were incorporated into the Finder along with File Sharing support. The limits of the resource manager were being overextended by the old style resource-based Desktop file. The Finder database file was redesigned as a file storing information in the data fork in a faster and more efficient form.

The primary information stored in the Finder's Desktop DB/Desktop DF files is the mapping of icon display information for application and their associated files. This includes application signatures (creators) and associated file types. This information is used by the Finder to determine what application to launch when a file is double-clicked and to ascertain whether a file can be opened by a drag'n'drop action onto an application.

Other files with their own icon information also have their icon mappings stored in this database. Several flags associated with every file, such as whether the file is an alias or stationery file, whether the file name is locked from change, and whether the file is visible or not are maintained in the database. Other information stored in these files includes Comments from Finder Get Info windows, position information of icons within Finder container windows, and the positioning of the Finder windows.

These are the files that are rebuilt by holding down the Command and Option keys during Finder startup.

More details about the Finder database can be found in Inside Macintosh:Macintosh Toolbox Essentials, chapter 7, Using the Finder Interface.

LisaDraw, MacDraw, MacPaint: White letters on a black background

This article has been archived and is no longer updated by Apple.

Need to put white letters on a black background? Well, just do the following.

MacPaint:

1. Select the text option from the pallet; select the font of your choice, then Outline or Shadow from the Style menu and type in your text.

2. Select the Paint Can from the pallet, then a shade of black. Move the pointer (now a small paint can) off to the side of your text and double click.

The Paint Can fills in the region around your text in black, leaving your typed characters white.

MacDraw or LisaDraw:

1. Type in your line, then change your letters to Outline or Shadow, with a fill of none.

2. Draw a box, circle, etc., over the top of your text.

3. While your box is still selected, select Send to Back from the Arrangement menu, then choose a fill of black.

The end result gives you white letters on a black background.

TA46436_ELF_VDTs_Health_and_Safety_Apples_Official_Policy_(TIL07837).pdf

ELF, VDTs, Health and Safety: Apple‘s Official Policy

What is Apple's policy regarding VDTs, electromagnetic emissions, and health?
This article has been archived and is no longer updated by Apple.
Apple Computer, Inc.
Corporate Statement on Video Display Health Issues
May 29, 1990

Apple's Corporate Position

Apple Computer is committed to making products safe. That's why we meet or exceed every safety standard, not because we have to, but because we want to. Based on the prevailing opinion of the scientific community, Apple believes that computer monitors are safe. However, with any scientific issue there is a diversity of opinion. We are open-minded to new scientific evidence and in fact encourage research in this area.

Apple's Monitoring Activity

Apple's products are constantly tested and compared against existing and proposed international standards. We continuously follow scientific developments in the field of computer health and safety. Members of Apple's Environmental Health and Safety group as well as representatives within Product Development, Product Marketing and Engineering Services keep track of new findings.

Apple is also a board member of the Center for Office Technology (contact is O. Bruce Dickerson 212-560-1298), a clearing house for more information related to health issues and office automation equipment. In addition, Apple is currently setting up a program to sponsor dedicated academic research in the low-frequency radiation field.

Scientific Opinion

The low level of intensity of the fields emitted from VDTs is not considered harmful by the American Medical Association, the American College of Obstetricians and Gynecologists, the National Institute for Occupational Safety and Health and the World Health Organization, among others.

Recently, the issue of the possible effects of prolonged exposure to extremely low frequency electromagneitc emissions has been raised. The U.S. Environmental Protection Agency has said (see New York Times 5/23/90) that the evidence on the issue is so far inconclusive. The EPA's office of health and environmental assessment has suggested further study on the ELF issue. Apple also supports additional research so that we can continue to act responsibly, ensuring the health and safety of our customers and employees.

Question and Answers

* What is Apple's position on the VDT-emission health issue?

Apple is committed to making products as safe as can be. Based on the prevailing opinion of the scientific community Apple believes that televisions and computers are safe. However with any scientific issue there is a diversity of opinion. We are open-minded to new scientific evidence and in fact encourage it.

* What are the health concerns regarding VDTs?

A number of studies link intensive computer use to health problems such as musculoskeletal disorders, eyestrain, fatigue, and headaches. These problems are well understood and medical experts have suggested effective methods for preventing them.

There is also a growing public concern throughout the world about potential health risks related to the low-frequency electromagnetic fields emitted by VDTs and other electric products, which all operate at the AC line frequency of 50 and 60 Hz such as electric blankets, televisions, and power lines.

Although most scientists and computer experts maintain that low-frequency electromagnetic emissions are harmless, others assert that not enough is known to say with certainty that they are safe. Most everyone agrees that more research is necessary before any conclusions can be made.

* What are the government regulations for VDT emissions?

X-ray emissions are strictly regulated by international law. In the US, this law is administered by the FDA's Dept. of Health and Human Services. All Apple displays are designed and tested to emit well below the level permitted.

Radio frequency emissions can interfere with radio and TV transmissions and are also regulated internationally. In the US, limits are mandated by the Federal Communications Commission.

In Sweden government-industry cooperatives have set limits for VLF radiation from VDTs. These limits do not appear to be based on data from

health studies, but rather are based on general, achievable guidelines for reducing emissions.

No government regulations exist in any country limiting ELF emissions.

* What is Apple doing to follow and participate in research in the VDT health field?

Apple's products are constantly tested and compared against existing and proposed international standards.

We continuously follow scientific developments in the field of VDT health and safety. Members of Apple's Environmental Health and Safety group as well as representatives within Product Development, Product Marketing and Engineering Services keep track of new findings.

Apple is a board member of the Center for Office Technology, a clearinghouse for information related to health issues and office automation equipment.

In addition, Apple is currently setting up a program to sponsor dedicated academic research in the low-frequency emissions field.

* How does Apple respond to increasing government legislative activity concerning VDT's?

We welcome government's inquiry into the safety of VDT's, and support the adoption of standards once generally agreed upon limits and a testing methodology emerge from research.

Product Issues

* Will Apple take steps to lower VLF and ELF emissions in its products?

Based on the prevailing opinion of the scientific community, we do not believe it is necessary to lower the ELF emissions of our computer monitors. In fact, scientific research so far has not been able to establish guidelines for emission levels. However Apple is closely following the issue so that we may continue to ensure the health and safety of our customers and employees.

* How might this radiation be reduced?

Currently emissions can be reduced through a combination of circuit board design, component selection, field cancellation coils, metallic shielding and surface coatings.

* Will you comment on IBM's announcement to lower emissions in its monitors?

IBM announced it will offer monitors which feature reduced VLF emissions. (See Wall Street Journal 11/22/89) They have clearly positioned these products as a response to market demand, rather than to health and safety concern. IBM's products are not currently shielded for ELF radiation.

* What are the levels of ELF and VLF emissions by Apple's VDTs?

Apple feels that it would be inappropriate to make these figures public because there is currently no standardized testing methodology or established guidelines by which to make comparisons.

* What is Apple's comment on the MacWorld article?

Regarding the Article: The MacWorld article calls for industry to address the VDT emission issue. Apple encourages further research on low-frequency emissions.

* Regarding the Measurements:

We do not believe it is appropriate to comment on the measurements of the Macintosh monitors that were published in the July 1990 issue because there is currently no standardized testing methodology or established guidelines by which to make comparisons.

* Regarding the Health Conclusions:

With any scientific issue there is a diversity of opinion. The MacWorld article excluded a large body of studies that discount a link between VDT use and a biological effect--for example: The University of Calgary, Alberta, Canada, 1989 Epidemilogical Study on VDT Use and Spontaneous Abortion Risk; The University of Toronto,1989 Rodent Reproductive Study; the Institute of Research for the Health and Safety of Workers, Montreal, Quebec 1984 Survey on VDTs and Pregnancy; and the 1985 Finnish Case Reference Study - Birth Defects and Exposure to VDTs During Pregnancy. The specific studies referenced by MacWorld raise valid questions but do not conclude a health risk for the computer user. We encourage futher scientific research.

Background on VDT Radiation

* What is radiation?

Are there different kinds? Radiation involves a transfer of energy by waves or particles. There are two types of radiation. Ionizing radiation, such as X-rays, has proven to be damaging to living cells. Non-ionizing radiation is far less potent, and includes visible light, radio waves, and low frequency electromagnetic emissions.

* What kind of radiation do VDTs emit?

Like television sets, VDTs may emit X-rays (ionizing radiation) at or near naturally occuring background levels. VDTs also give off non-ionizing radiation in the form of infrared light (heat), visible light, radio waves, and low frequency electromagnetic emissions. Apple's displays do not give off ultraviolet or microwave radiation in appreciable levels.

* What is ELF and VLF radiation?

Low-frequency radiation, a form of non-ionizing radiation, is generally divided into two groups: very low frequency (VLF) and extremely low frequency (ELF). VLF radiation falls into the frequency bandwidth between 30 and 150kHz, while ELF radiation refers to frequencies below 30 kHz. The intensity level of this radiation emitted by VDTs is comparable to that emitted by household electrical appliances.

* Is VLF or ELF radiation dangerous?

The prevailing opinion of the scientific community is that exposure to low frequency emissions does not pose a significant health risk. Available data indicate the human body absorbs only a minimal amount of radiation below 200 kHz. The low level of intensity of the fields emitted from VDTs is not considered harmful by the American Medical Association, the American College of Obstetricians and Gynecologists, the National Institute for Occupational Safety and Health (NIOSH) and the World Health Organization, among others.

However, with any scientific issue there is a diversity of opinion. There are several studies which suggest that long-term exposure to pulsed ELF fields (such as those emitted by VDTs) can result in biological changes to cells.

Because valid questions have been raised, Apple encourages further research on low frequency radiation. In fact, we are currently setting up a program to sponsor dedicated academic research in the low-frequency radiation field. We intend to continue monitoring the results of this research so that we can act responsibly to ensure the health and safety of our customers and employees.

AppleShare: Server Startup with External Drives Attached

The Macintosh that I'm using as an AppleShare server has an internal hard disk and two external volumes. In case of a power failure, I have the server set restart automatically. The problem is that the Macintosh checks for the external SCSI drives before the drives are ready.

Is there a way to make the server wait 30-60 seconds before checking for SCSI devices?

This article has been archived and is no longer updated by Apple.
There is no way to have the server wait before it looks for available drives. The server waits for Drive 0 to be ready, though. By the time Drive 0 is ready and loaded, the other drives should be ready to mount.

Macintosh: Definition of System Heap

What is a "system heap"?

This article has been archived and is no longer updated by Apple.
The system heap is a special area of RAM set aside for things like fonts and DAs. The heap zone is used mostly by operating system data structures. The heap zone is an area in memory that may be allocated in relocatable and non-relocatable pieces, called heap blocks or heap pieces. The heap zone usually begins at $B00 and extends to $CAFF, but you should not count on those addresses being correct.

If you ever see an error message with the number -108, it probably means you need more space in your system heap. Increasing its size will help you if you have many fonts and DAs.

Apple Writer IIe: Converting DOS files to ProDOS

This article describes how to convert Apple Writer IIe DOS files to ProDOS.
This article has been archived and is no longer updated by Apple.
To convert Apple Writer IIe DOS files to ProDOS, first print your files to disk:

1. Insert your destination diskette into the drive.

2. Press "p" while holding down the Control key.

3. Type in PD8 Return.

4. Press control P again, then press NP to begin printing to your disk.

5. Enter your file name when prompted. Don't forget to type the disk drive and slot number if necessary.

Note: You type PD8 because there is no slot 8 in an Apple IIe. This alerts Apple Writer to print to a disk and ask you for a file name.

Now convert your file from DOS to ProDOS using the Apple IIc Utilities disk (part number 680-3234) or the CONVERT program on the the ProDOS User's disk (part number 680-0224).

TA46440_System_Improving_Performance_on_the_Macintosh_IIsi_and_IIci_(TIL07840).pdf

System 7: Improving Performance on the Macintosh IIsi and IIci

Why do the Macintosh IIsi and IIci seem so slow with 256 colors or shades of gray? I am running System 7.

This article has been archived and is no longer updated by Apple.
This is due to the video RAM in the 1MB RAM bank A (soldered on the logic board on the Macintosh IIsi). Using 256 colors makes this bank of RAM very busy (the more colors the busier). Consequently, access to anything else in this part of memory is slow.

Macintosh IIsi

On the Macintosh IIsi, adjust the RAM cache to at least 384K. As a result, bank A is all video RAM, RAM cache, and RAM used by the System. This makes the performance with 256 colors almost as good as with black and white. Setting the RAM cache higher than 384K does not help much. This will also work with the Macintosh IIci if you have four 256K SIMMs in RAM bank A.

Macintosh IIci

On a Macintosh IIci, if Bank A is not filled with 256K SIMMs (instead, it is filled with 512K, 1MB, 2MB, 4MB or 16MB SIMMs) it is harder to keep applications from sharing that RAM bank which is busy. You can try to boost the RAM cache to approximately the size of the memory in RAM bank A minus 600K and get similar results, but this takes memory away from your applications.

System 7: Desktop Manager and Switching Between System 6 & 7

I need to switch between System 6.0.x and System 7.x because I use some applications that are incompatible with System 7.x. Is there a way to avoid rebuilding the Desktop file every time I switch System files?

This article has been archived and is no longer updated by Apple.

```
Yes, you can use the Desktop Manager INIT (v2.0.1) to switch between
System 6 and System 7 without rebuilding the Desktop file.  You can find
the Desktop Manager INIT on the AppleShare Administration disk in the
System Folder.  The Desktop Manager Engineer confirmed that it is safe to
use.  Just put the INIT in your System 6 System Folder.  DO NOT put
the INIT in your System 7.x System Folder.

NOTE: The Desktop Manager INIT is not available to everyone.  It is
licensed only to users who have AppleShare 2.0.1. You can find the Desktop
Manager 2.0.1 INIT on the AppleShare Server disk inside the System Folder.

Article Change History:
24 September 1993 - Revised article, clarifying where to obtain the Desktop
                    Manager 2.0.1 INIT.

System 7: Disk Format Can‘t Be Done in Background

Within System 7, can I start formatting a disk and then switch to a program that is already running?

This article has been archived and is no longer updated by Apple.

No. Although some Finder operations, such as copy, work in the background, format does not run as a background task. It is timing dependent and needs to keep control of the system.

Published Date: Feb 18, 2012

System 7: Temporarily Disabling Virtual Mem. at Startup

Is there a way to turn off System 7.x Virtual Memory at startup without disabling the system extensions?
This article has been archived and is no longer updated by Apple.
Yes, holding down the Command key at startup will disable Virtual Memory but still load system extensions. When you restart the system, Virtual Memory will be turned on again.

If you check the Memory control panel after booting with the Command key held down, it will show Virtual Memory On and also show how much memory will be available on restart.

System 7: 24-bit Addressing with More than 8MB of RAM

Article Change History

08/21/92 - REVIEWED
* For technical accuracy; edited.

How does the Macintosh operating system handle more than 8MB of physical RAM when it is not using 32-bit addressing?

This article has been archived and is no longer updated by Apple.

When a Macintosh is running in 24-bit mode (that is, when System 7's 32-bit Addressing is turned off or the Macintosh is running System 6.0.x) any physical memory over 8MB is allocated to the System, provided the Macintosh can see the memory in the first place, but it's not actually used. Even though the hardware can see all of the physical RAM, 24-bit addressing allows the use of only 8MB. You may see a large System allocation when checking "About this Macintosh" or "About the Finder" and think something is wrong, when in fact this is the way it should work.

System 7's 32-bit Addressing allows up to 1GB of total memory (including both physical and virtual memory).

System 7: Defaults for Labels Control Panel Colors

Article Change History

09/11/92 - REVIEWED
* For technical accuracy.

How can I reset the colors of my Labels settings to the original defaults?

This article has been archived and is no longer updated by Apple.

To reset the colors, either remove the existing System file and reinstall System 7, or manually reset the values.

To manually reset the values, open the Labels control panel, click on the color bars displayed on the left, and set the default values as follows:

Color for "Essential"
Hue: 4223
Saturation: 64884
Brightness: 65535
Red: 65535
Green 25738
Blue 652

Color for "Hot"
Hue: 108
Saturation: 63573
Brightness: 56683
Red: 56683
Green 2242
Blue 1698

Color for "In Progress"
Hue: 59733
Saturation: 63286
Brightness: 62167
Red: 62167
Green 2134
Blue 34028

Color for "Cool"
Hue: 35756
Saturation: 64907
Brightness: 60159
Red: 577
Green 43860
Blue 60159

Color for "Personal"
Hue: 43690
Saturation: 65535
Brightness: 54272

System 7: LaserWriter Driver and Adobe Font Downloader

Article Change History

09/17/92 - UPDATED
* With contact information.

I receive the error message "Couldn't open the printer driver" when trying to use Adobe's Font Downloader under System 7. How do I fix this?

This article has been archived and is no longer updated by Apple.

Font Downloader expects the LaserWriter driver to be in the System Folder, while System 7 normally installs it in the Extensions folder. Simply move the LaserWriter icon from the Extensions folder into the System Folder to correct this problem. System 7 will still be able to locate the LaserWriter driver without a problem.

For the most current information on Adobe Font Downloader, including upgrades that may change this situation, contact Adobe directly. To locate Adobe's address and phone number, use the vendor name as a search string.

System 7: Installing Adobe Font Library

This article gives instructions for installing the Adobe Font Library on a Macintosh running System 7.

This article has been archived and is no longer updated by Apple.

```
*  To install bitmap (screen) fonts, simply drag the font suitcase to the
   System Folder icon and System 7 will automatically install them in the
   System file.  System 7 does not require Font/DA Mover to install bitmap
   fonts.

*  To install outline (printer) fonts, simply drag the font icons (not the
   folder containing them) to the System Folder.  System 7 will
   automatically install them in the Extensions Folder.

NOTE: If you are using a version of Adobe Type Manager prior to 2.03, you
must move outline fonts from the Extensions Folder to the System Folder to
work properly. If you are using 2.03 or later, ATM should work properly
with outline fonts inside the Extensions folder - but make sure to
completely remove older versions of ATM before installing the updated
version.
```

TA46449_System_What_Happens_to_Your_Old_Fonts_(TIL07851).pdf

System 7: What Happens to Your Old Fonts

Article Change History

09/02/92 - REVIEWED
* For technical accuracy; edited.

What happens to the fonts already installed in my System 6.0.x System when I upgrade to System 7?

This article has been archived and is no longer updated by Apple.

Bitmapped fonts already installed in the System file will remain there.

PostScript fonts located in the System Folder will remain there. PostScript fonts installed after an upgrade to System 7 (by dragging them over the System Folder icon) are placed in the Extensions folder.

Published Date: Feb 18, 2012

System 7: How to Install and Run Adobe TypeAlign

Article Change History

09/02/92 - REVISED
* To be more clear and with version information.

When I access TypeAlign, I get the error message "TypeAlign can't run until you have rebooted with the TypeAlign Startup in your System Folder". Is there a special way to install this program under System 7?

This article has been archived and is no longer updated by Apple.

Installing Adobe TypeAlign under System 7 is similar to installing it under previous versions of the Macintosh operating system. Here are the steps:

1) Drag the TypeAlign, TypeAlign Startup, and TypeAlign Help icons from the master floppy disk to your System Folder.

2) When "Some of these items need to be stored in special places... Put them where they belong?" dialog appears, click OK. The system will place TypeAlign in the Apple Menu Items Folder, TypeAlign Help in the System Folder, and the TypeAlign Startup in the Extensions Folder.

3) In order for TypeAlign to run properly, move the TypeAlign Startup icon from the Extensions Folder to the root level of the System Folder.

Note that at least TypeAlign version 1.0.5 is available. Contact Adobe for the most recent version information.

Published Date: Feb 18, 2012

System 7: Adobe Type Manager 2.0 and 32-bit Addressing

I'm using Adobe Type Manager 2.0 and 32-bit addressing under System 7. The system crashes whenever I select a font menu. What is the workaround?

This article has been archived and is no longer updated by Apple.

The workaround is to disable 32-bit addressing. Adobe Type Manager 2.0 is compatible with 24-bit addressing, but incompatible with 32-bit addressing under System 7. Upgrade to a more recent version of ATM (at least 2.03), for 32-bit addressing to work properly.

System 7: TypeAlign "Font Not Available" Error

Article Change History

09/02/92 - UPDATED
* To provide contact and version information.

The error message, "Outline Font Not Available" appears when I enter text into TypeAlign running under System 7. What causes this?

This article has been archived and is no longer updated by Apple.

```
This can be caused by two things:

* The outline (printer) fonts may be in the wrong location.  Open the
 System Folder and verify that the outline fonts are there.  If not,
 locate them and move them to the System Folder.

* If you are using TrueType versions of Helvetica, Courier, Times, and
 Symbol, TypeAlign will be unable to find an Adobe Type 1 version.
 TypeAlign currently does not support TrueType.  Either remove the
 TrueType version of the font or use an Adobe Type 1 font instead.

For fullest compatibility, you should be using at least 1.0.5 of Adobe
TypeAlign. Contact Adobe for the latest information; search for Adobe for
contact information.
```

System 7: DataDesk Keyboard Compatibility

This article gives compatibility information for DataDesk keyboards used with System 7.
This article has been archived and is no longer updated by Apple.
Some older DataDesk Macintosh 101 keyboards do not allow you to disable extensions under System 7 by holding down the Shift key during startup. There is no known workaround for this problem, short of temporarily replacing the DataDesk keyboard with an Apple keyboard.

Specific compatibility issues:

* Macintosh 101 Keyboard (Macintosh Plus) Version 1.0
Incompatible INIT - Currently won't recognize any keys pressed during startup. Requires an upgrade to use extended part of the keyboard.

* Macintosh 101 keyboard (ADB) Version 1.0
No INIT is needed - Won't recognize any keys pressed during startup.
This keyboard is likely to be at least three years old.

* Macintosh 101 Keyboard (ADB or Macintosh Plus) Version 1.1
Compatible with System 7.

* Macintosh 101e Keyboard (ADB or Macintosh Plus)
Compatible with System 7.

* Macintosh Switchboard (ADB or Macintosh Plus)
Compatible with System 7.

For further information, contact DataDesk. The address and phone number is in a separate article in the Tech Info Library.

System 7: Initialize Drive if Disk First Aid Can‘t Repair

Article Change History

08/24/92 - REVIEWED
* For technical accuracy.

What should I do if Apple's "Disk First Aid" utility reports that it is unable to repair a disk's directory?

This article has been archived and is no longer updated by Apple.

If the Macintosh has been started up with the System 7 "Disk Tools" floppy disk and Disk First Aid cannot repair a hard drive's directory, the drive must be reinitialized with an appropriate formatting utility. Apple hard drives are initialized with Apple's HD SC Setup utility. Third-party hard drives require System 7-compatible initializing/formatting software supplied by the vendor.

IMPORTANT: Before initializing the drive, make at least one backup of the drive using System 7-compatible backup software, otherwise you will lose everything on the drive.

HyperCard: Importing and Exporting Text, and Where To Get Info

Here is a button script that imports text data into HyperCard. The data source is a text file with the following format:

data<tab>data<tab>.....data<tab>data<carriage return>
data<tab>data<tab>.....data<tab>data<carriage return>
data<tab>data<tab>.....data<tab>data<carriage return>
This article has been archived and is no longer updated by Apple.
This script reads data and puts it into a field in the card where the button is. It moves to the next field when it encounters a tab, and makes a new card after a carriage return. This script requires that the number of fields in your card equals the number of data items you want to import.

```
on mouseUp
ask "Import text from what file?" -- Ask user for name of source file.
if it is empty then exit mouseUp
put it into fileName -- "put" and "open" open the text file for reading.
open file fileName
repeat -- Data is imported in the "repeat" loops.
doMenu "New Card" -- Make a new card.
repeat with i = 1 to the number of fields - 1
read from file fileName until tab -- Read text from the file until Tab
-- character is encountered.
put empty into last char of it -- Remove Tab.
put it into field i
end repeat
read from file fileName until return
if it is empty then -- end of file
if i = 1 then doMenu "Delete Card"
close file fileName
exit mouseUp
end if
put empty into last char of it -- remove Return.
put it into field (i + 1)
end repeat
end mouseUp
```

When the first tab is encountered, the tab is removed from the string and the data is placed in field one. This is done until the next to last field, because we have to look for a carriage return at the end of the last field. We then read in data until a carriage return occurs, and the data is placed into the last field of the card.

This script has been used to import data files 500K and larger into HyperCard. It may have to be changed to work with a specific data file or format.

You can also EXPORT text from HyperCard fields into a text file. You can tab delimit the fields, or use any character you want:

```
on mouseUp
ask "Export text to what file?" -- Ask user for name of source file.
if it is empty then exit mouseUp
put it into fileName -- "put" and "open" open the text file for reading.
open file fileName
repeat with i = 1 to the number of cards -- go through all the cards
go to card i
repeat with j = 1 to the number of fields - 1
write field j to file fileName -- get the field and write it out
write tab to file fileName -- put a tab after it,
-- or any character you want
end repeat
write field (j + 1) to file fileName -- write the last field
write return to file fileName -- and a carriage return
end repeat
close file fileName
end mouseUp
```

This would export the data you had just imported with the first script.

NOTE: This second script has NOT been extensively tested.

ANOTHER NOTE: This is NOT the only way to import & export data: use it as a guide for your own scripts. These examples were chosen because tab-delimited data is a common format. HyperCard offers a large amount of flexibility in reading data in and out, and it would be impossible to describe all the different methods in this article. There are various sources of information regarding the HyperTalk scripting language.

For more information:

- HyperCard's Help stack (look for "ask", "put", "open", "write", "repeat", and "doMenu")
This part of HyperCard is often overlooked. The built-in help has descriptions of the HyperTalk commands available to you, and is on-line.

- "HyperCard Script Language Guide" (APDA)
This is the definitive guide to the HyperTalk scripting language. It contains descriptions to all the HyperTalk commands available, and also discusses the HyperCard environment.

- Danny Goodman's "The Complete HyperCard Handbook" (Bantam)
This was the first book available as a reference for HyperCard, and covers the tools available in HyperCard, as well as how to use the scripting abilities. It also has example scripts.

- Additional third-party books.
You should be able to find various other books on HyperCard at a local computer bookstore.

- The User Groups Icon on AppleLink.
This icon is a meeting place for Apple dealers and user groups to exchange information relating to Apple products.There is also a HyperCard folder, devoted to questions and answers and public domain and shareware utilities and stacks for HyperCard.

System 7: Using Personal LaserWriter SC and LaserWriter IISC

I've installed System 7, and now I can't print to my LaserWriter IISC. The installer did not replace my old LaserWriter SC driver. I keep getting print errors when I use the driver that came with the printer. How do I fix this?

This article has been archived and is no longer updated by Apple.
The LaserWriter IISC printer software is not compatible with any version of System 7. You might be able to print using the LaserWriter IISC print driver if background printing is turned off, but this is not recommended. To permanently fix this problem, you need to use the Personal LaserWriter SC printer driver from the Printing disk to print to this printer.

Copy the Personal LaserWriter SC driver from the System 7 Printing disk to the Extensions folder on your startup volume. Select the Personal LaserWriter SC icon in the Chooser.

You can use the Personal LaserWriter SC driver with both the Personal LaserWriter SC and the LaserWriter IISC. This is true for versions prior to System 7 as well.

Article Change History:
24 Aug 92 - Incorporated similar articles and clarified that the Personal LaserWriter SC driver is the same as the LaserWriter IISC driver.
11 Jul 94 - Clarified that the LaserWriter IISC driver is not system 7 compatible.

System 7: CD Technology Drive and CD Setup

Article Change History

09/02/92 - UPDATED
* To give contact information.

I have a CD-ROM drive from CD Technology, Inc. After I load System 7 on my Macintosh IIfx, and run the installer on the Macintosh CD Setup disk as instructed in the Group Upgrade Guide, I cannot connect the CD-ROM drive. How can I connect the CD Technology ROM drive?

This article has been archived and is no longer updated by Apple.

```
The CD Technology CD-ROM drive uses the system access modules on the System
7 CD Setup disk, but not the driver.  After running the installer, delete
the Apple CD-ROM and Apple CD Remote from the Extensions folder.  Install
the CD Technology driver version 1.32 (or later) in the System Folder.

NOTE: CD Technology version 1.32 causes system errors on 68000-based
systems, but works correctly on 68020- and 68030-based systems.

Contact CD Technology, Inc. for the most recent information on their
product; search on CD Technology for contact information.

System 7: Cannot Be Installed on a 1MB Macintosh

Article Change History

08/17/92 - REVIEWED
* For technical accuracy.

Can I install System 7 on a Macintosh system with one megabyte of RAM?

This article has been archived and is no longer updated by Apple.

No. The System 7 Installer will not run on a one megabyte Macintosh. It will give an error message stating the machine does not have enough memory to run System 7.

Published Date: Feb 18, 2012

Macintosh System Software 6.0.7: Troubleshooting (1 of 2)

This article outlines the steps for troubleshooting system software version 6.0.7. Perform these operations in the order presented here.
This article has been archived and is no longer updated by Apple.

WDEF Virus

The number one known problem is the WDEF virus. In version 6.0.5 and earlier versions of the system software, the WDEF virus might exist without creating major problems. This is not true in version 6.0.7. The presence of the WDEF virus can cause problems from the moment the computer is turned on. The most common results are the three error messages - "Bus Error," "Address Error," and "Coprocessor not Installed." Floppy disk copy procedures are known to suffer in particular, but the difficulties can appear at any time without any warning.

Solution:
Use Disinfectant 2.4 (or later) or SAM 2.0.5 (or later) to detect and remove the WDEF virus. Disinfectant is available from various online services. SAM is available from Symantec. Other anti-virus applications may also assist in detection and removal.

Incompatible Applications

Incompatible applications cause the next most common problem. Older versions of applications are often incompatible. Some of the most commonly reported incompatibilities have been with Microsoft Works 2.00a and MacWrite 5.0x. Fully compatible versions of these two programs are Microsoft Works 2.00e and MacWrite II 1.1v2.

An application that causes things to go wrong may not be the application that is currently running; it may be an application that ran previously. An application might corrupt some portion of memory and then never reference that area of memory during the remainder of its running time. However, an application launched later (possibly, an application that tested as compatible) may make a reference to the corrupted memory created by the earlier application. The result is a system error, most likely one of the three previously mentioned - "Bus Error," "Address Error," or "Coprocessor not Installed."

Solution:
Check with the publisher of any software package you are wondering about concerning compatibility with the 6.0.7 environment.

INITS and CDevs

The next possibility is closely related to applications. INITs and cdevs can be considered mini-applications. INITs are programs that run at startup and continue to run during the entire time that the Macintosh is on. Some cdevs can have a split personality. First, a cdev can exist only as a Control Panel item; but second, a cdev can also contain an INIT that may not be visible to the user.

Other cdevs that do not contain an INIT will not affect the operation of the system unless they are chosen from the Control Panel. This form of cdev can be thought of as a mini-program. If it isn't chosen by the user, it isn't run.

INITs and cdevs that contain INITs, are a different matter. They can affect a system from the early part of the startup process. If there are any incompatibilities with these items, a system can display error dialogs at any time. Then again, depending on what has been done since the Macintosh was started up, they may never cause any problem.

Solution:
Remove all INITs and cdevs that were not installed by Apple's System Software Installer program. Then test the Macintosh to see if the previous difficulties have gone away.

If the difficulties have gone away, and you must have the use of INITs and cdevs, reinstall one INIT or cdev at a time and then test for difficulties after each installation. Repeat this sequence until after the installation of one of the INITs or cdevs difficulties begin appearing. Then take one step back and remove the last installed INIT or cdev. Check with the publisher of that removed item to see if a later and compatible version is available. If it isn't, you will need to find a way to achieve those functions in a different manner until the publisher can provide an update.

Third-Party SIMMs

Some third-party SIMMs do not meet Apple's specifications. There are two SIMM issues listed here.

1) The PC board on which the RAM chips are mounted is too thin to provide proper contact to both sides of the SIMM socket. The results are system error dialogs. There appears to be a very small sample of boards that are affected by this issue.

2) The timing of the PAL chip on some SIMMs has proven to be out of specification. The 2MB SIMMs appear to be the most common offenders. Timing issues can also result in system error dialogs. Third-party vendors have been informed of the considerations involved with timing.

Solution:
To determine if the SIMMs are at fault, replace the third-party SIMMs with Apple SIMMs and run tests to see if the previous problems continue. If the Apple SIMMs resolve the appearance of system error dialogs, replace the SIMMs.

Hard Disk Drivers

Hard disk driver software can have trouble performing correctly when installed in certain ways, or if the driver software is out of date. This is a problem with either Apple HD SC hard disks or various third-party hard disks. Before reinstalling system software, try this step, which is not as involved as doing a system software reinstallation.

Solution: Procedure for Apple Hard Disks
Use the Apple HD SC Setup that ships with 6.0.7 (or later) to update the river on the hard disk. The version of this hard disk driver is at least 2.0.3. Use the Drive button to select the hard disk that will be the startup disk. Press the Update button to update the hard disk driver software on the hard disk.

Solution: Procedure for Third-Party Hard Disks
Some third-party hard disk drivers which are installed with an "Installer" type of program may have difficulties if the installer was launched from a System 6.0.5 (or earlier) environment.

Usually this means that the third-party installer was shipped on a floppy disk which has System 6.0.5 (or earlier) on the disk. The installer disk is used to boot for the installation. In this way, the hard disk driver is installed from 6.0.5 (or earlier) into 6.0.7. Sometimes a Macintosh system which has been in place for a while is updated to version 6.0.7. The third-party hard disk drivers were in place prior to the 6.0.7 update.

In either case, follow these steps to resolve the problem:

1) Create a third-party hard disk installer disk with System 6.0.7 (not 6.0.5) on it. Make a new installer disk or update the installer disk to version 6.0.7.

2) Boot from the third-party hard disk installer with 6.0.7 on it.

3) Launch the third-party hard disk installer.

4) Update the third-party hard disk's driver. (Most installers have an Update selection.)

5) Restart and test for previous difficulties.

If you have worked through all of the procedures described in this document and you still have problems, you need to reinstall System Software 6.0.7. Search for the second part of this article on System 6.0.7 Troubleshooting for advice on reinstalling the system software.

For information on downloading the latest version of Disinfectant refer to:
TIL aritcle 30487: "**Disinfectant: Macintosh Anit-Viral Utility**"

The Tech Info Library article#17159: "**Locating Vendor Information**", can help you search for a particular vendor's address and phone number.
Published Date: Feb 18, 2012

Macintosh System Software 6.0.7: Troubleshooting (2 of 2)

If the difficulties persist after you work through the four steps outlined in part 1 of this article, review the installation of the system software. This document (part 2 of the article) gives the proper procedures for reinstalling system software 6.0.7.
This article has been archived and is no longer updated by Apple.
Do not use Minimum Install. The Minimum Install option of the System Software Installer is meant for creating bootable floppy disks and may not contain all the resources you need for a complete system.

You may install using the "Easy Install" option or by customizing which system resources are written to your disk. Below is the first of two custom installation procedures.

1) Start up from the Installer floppy disk. (800K=System Tools; 1.4MB=System Startup).

2) Remove from the System Folder any items that you wish to save, and that weren't installed with Apple's Installer.

3) Drag the System Folder to the Trash.

4) Empty the Trash.

5) Launch the Installer. Now you have the choice to do an Easy Install, or to customize your installation. This will be more involved, but may be the best approach. To do this, click on the Customize button. This will present a scrolling text field. Here are the choices you must make:

- AppleShare (workstation software)
- Software for AppleTalk Responder
- 32-Bit QuickDraw
- Printer
- Model of Macintosh

You will want AppleShare if you are using AppleShare file servers. The network administrator may want you to have AppleTalk Responder. Some applications (usually graphic programs) require 32-Bit QuickDraw. You will need to know which printer to use. In the case of the ImageWriter, you need to know whether it is an AppleTalk network printer or a locally attached printer. And finally, you will need to know which model of Macintosh you are using.

Shift-click on each of the choices in the scrolling text field.

6) Make sure you see the disk displayed on which you want to install the system software, and click the Install button.

The following steps are for the second custom installation method. Use this procedure with understanding and caution. This solution is not verified, however it solved difficulties with 6.0.7 at certain sites. This is more involved than the last procedure, and requires more patience when trying this sequence. Certain rules appear to be violated, but for good reasons.

1) Start up from the Installer floppy disk. (800K=System Tools; 1.4MB=System Startup)

2) Remove from the System Folder any items that you wish to save, and you didn't install with Apple's Installer.

3) Drag the System Folder to the Trash.

4) Here is where the rules are bent. Empty the Trash and drag a copy of the System Folder from the Installer floppy disk onto the hard drive. BUT don't stop here! Now continue with step 5 of the first custom installation sequence.

There are no guarantees with this procedure. But it is worth the time if you continue to have difficulties.

If you still have difficulties after attempting all of these procedures, make backups of all important files. Then reformat the hard drive and reinstall system software 6.0.7. On Apple hard disks be sure to use Apple HD SC Setup v2.0.3 or later to reformat (reinitialize). For third-party hard disks, use their formatting or installation software.

If you continue to have problems, ask your service provider to check for hardware problems.

Macintosh System Software 6.0.7: Compatibility Report (6/95)

The following is a list of third-party software applications that Apple tested with system software 6.0.7. This list should be used as a snapshot of compatibility as of the day of 6.0.7 introduction.

This article has been archived and is no longer updated by Apple.
This report does not cover all Macintosh application software, it covers only those applications that Apple reviewed. For more detailed information on compatibility of an application and system software 6.0.7, contact the developer or publisher of that product.

Apple did not test every feature of the application. Instead, each application was run through a series of common functions: launch, open a simple document, open DAs, cut/paste, and print).

This report reflects compatibility information on the version number of the application listed, and in some instances does not reflect the most currently available version of a particular application. This list is not intended as an endorsement nor advertisement of any product. This list is meant to provide you with the most current information regarding compatibility of system 6.0.7.

Note:
Testing was done on the Macintosh Classic, Macintosh LC, Macintosh IIsi, Macintosh Plus, Macintosh SE, Macintosh SE/30, Macintosh IIcx, Macintosh IIx, Macintosh IIci, Macintosh IIfx, and Macintosh Portable personal computers using system software 6.0.7 . Ratings for all applications indicate performance of the application running on released CPUs and released system software.

The following products passed our compatibility tests. If any additional comments were needed, then they are mentioned in the "COMMENTS" field.

AppleShare File Server: Allowing Apple II Network Startup

This article tells how to set up your AppleShare File Server software so that Apple IIGS and Apple IIe systems can start up over the network.

An earlier version of this article appeared in the June 1990 "TechBeat" and in the "Apple II Tech Bulletin" for February-March 1990. Since then, new versions of the Apple IIGS and Macintosh operating systems have been released, requiring updated documentation.

This article has been archived and is no longer updated by Apple.
Assuming the hardware is already set up, the installation process should take from one to two hours. This article assumes you are installing AppleShare on a newer Macintosh running System 6.0.7. Note: If you are installing on one of the older Macintosh computers, for example an SE/30, System 6.0.5 would be an acceptable replacement for System 6.0.7.

This article also applies to those with existing AppleShare File Servers. Where necessary, we will explain what material to skip over.

Besides Macintosh system software, you need the AppleShare File Server software (version 2.0.1), Apple part number M0548/B. Finally, you need Apple IIGS System Software Update Version 5.0, Apple part number A0013LL/A. (This version is now shipping with version 5.0.4 in the box.)

Note that IIGS System 5.0.4 is a three-disk set. The third disk, a Macintosh disk called "Apple II Setup", is essential. You will need to buy at least one IIGS System 5.0 Software Update, because this third disk does not ship with new IIGS systems. Table 1 lists the disks required. You also need one blank 800K disk.

Note: For future reference, if a new version of IIGS system software is released, use the complete three-disk set from that system instead of version 5.0.4.

Table 1: Required Disks

Disk Name Format Comment

System Startup 6.0.7 Mac 1.44MB
System Additions 6.0.7 Mac 1.44MB
Network Products Installer 6.0.7 Mac 1.44MB

AppleShare File Server 2.0.1 Installer Mac 800K Part of A'Share 2.0.1.
AppleShare File Server 2.0.1 Admin Mac 800K Part of A'Share 2.0.1.
Apple II Setup 2.0.1 Mac 800K Part of A'Share 2.0.1.
-->Obsolete disk!

/System.Disk ProDOS 800K Part of IIGS System 5.0.4.
/System.Tools ProDOS 800K Part of IIGS System 5.0.4.
Apple II Setup 2.1.3 Mac 800K Part of IIGS System 5.0.4.
-->New version.

1. Setting up the AppleShare File Server

Follow these steps to set up the AppleShare File Server:

1) If you have an existing server, start up from the Network Products Installer disk and install "Apple II Setup (v2.0.1)". (Others should skip to the next paragraph.)

2) When the Installer prompts you for the "Apple II Setup" disk, insert the Apple II Setup version 2.1.3 disk that came with IIGS System Software 5.0.4.

Do not insert the obsolete Apple II Setup disk that comes in the box with AppleShare 2.0.1. For those with an existing file server, proceed to Section 2, "Preparing AppleShare for Apple II Users".

If you haven't set up your server yet, here is how to do it:

1) Boot the Macintosh with the System Startup disk

2) Launch HDSC Setup and initialize the hard disk. When giving the hard disk a name, use a short name that fits ProDOS conventions. The name must begin with a letter (A to Z) and contain nothing but letters, numerals and periods. No spaces. Lower case is permitted. For this example, we will name the server volume "A2".

3) After the hard disk has been initialized, quit HDSC Setup and launch the Installer. Click "Easy Install".

4) When the installation is complete, quit the Installer.

5) Double-click on the hard disk icon and open the System Folder.

6) Drag "Easy Access," and any printer drivers you don't need, to the Trash. You can also delete MultiFinder. If you won't be doing any printing from the file server, you can throw away Backgrounder and PrintMonitor.

7) When you are done, select "Empty Trash" from the Special menu and close all open windows. Then select "Shut Down" from the Special menu.

With the cleanup out of the way, it's time to install the software:

1) After the Macintosh ejects the System Startup disk, restart from the Network Products Installer disk.

2) Launch the Installer and select "AppleShare File Server (v2.0.1)" and holding down the Shift key, select "Apple II Setup (v2.0.1)".

3) Click Install. The Installer will prompt you for the "AppleShare File Server" disk (that's the AppleShare Installer disk), and shortly thereafter, the "AppleShare Administration" disk.

4) When it prompts you for the "Apple II Setup" disk, insert the Apple II Setup version 2.1.3 disk that came with IIGS System Software 5.0.4.

Important: Do not insert the obsolete Apple II Setup disk that comes in the box with AppleShare 2.0.1

5) When the Installer is finished, quit and restart the Macintosh, letting it start up from the hard drive.

6) The hard drive isn't an AppleShare File Server yet, so you must set it up. Open the System Folder on the hard drive and double-click "AppleShare Admin".

7) When asked if you want to "Prepare volume 'A2' for use with AppleShare?", click OK. You'll be asked to give the file server a name, for example, "Apple II Forever".

8) Next, the system will prompt you for a Users and Groups file. Open the Server Folder and click "New". Create users and groups according to your needs and preferences, starting with the Administrator.

9) When you are done, select "Save Users and Groups as ╔" from the File menu and save the Users and Groups in the Server folder.

2. Preparing AppleShare for Apple II Users

Here's how to prepare AppleShare for Apple II Users:

1) If you haven't done so, get into the AppleShare Admin program. (There is no need to shut down your server to do this.)

2) Under the Server menu select "Server Info" and click on the check box marked "Apple II Features".

3) Click "Save". Quit the AppleShare Admin program.

4) If you were updating an existing file server, shut down the server and restart. Others can merely select "Restart" from the Special menu to restart the Macintosh. It will come up as an AppleShare File Server.

If you want the file server to support network startup only for Apple IIe users, the server is now ready to start them up over the network, once you set the access privileges on the volume. Users must be able to "See Files, See Folders" to start up.

To set the access privileges, follow these steps:

1) Get into AppleShare Admin and select "Volume List" from the Volume menu.

2) Double-click the server volume.

3) Set the access to "See Files, See Folders" and apply the changes to all enclosed folders -- unless you have an existing file server, in which case you will probably need to assign access by folder.

Apple IIe users need "See Files, See Folders" access to the top level of the server startup volume. Whether you set these changes for the Administrator only, all users, or just the particular groups, depends on how you have planned your server.

If you want IIGS users to be able to start up over the network, you should continue with the next section, which tells you how to install IIGS system software onto the server, over the network. This step is required only if the IIGS users will be starting up over the network. If the IIGS workstations have hard drives, you should set them up to start up GS/OS on their hard drives, and install AppleShare. This way, they can mount server volumes on the desktop, just like Macintosh users.

3. Installing IIGS System Software over the Network

Make sure you have the AppleShare File Server and the Apple IIGS connected via LocalTalk or similar network cabling. The IIGS should have a minimum of 1MB of RAM and one Apple 3.5 Drive. (You'll save time if you equip the IIGS with two Apple 3.5 Drives.)

When you turn on the IIGS, hold down the Control Open-Apple Escape keys to get into the text Control Panel. If you have defined a RAM disk, make sure you leave the system with at least 1MB of memory. Under Slots, ensure that the Startup Slot is set to 5, and that Slot 5 is set to "SmartPort" and Slot 7 to "AppleTalk" or "Built-In AppleTalk". Slot 1 should be set to "Your Card", or on a ROM 03 IIGS to "Built-In AppleTalk". Exit from the Control Panel and turn off the computer.

Be sure you have the original (unmodified) System.Disk and System.Tools diskettes. Lock both diskettes to prevent accidental deleting of critical files. You will also need one blank 800K disk to use as an AppleShare startup disk. Follow these steps:

1) Insert the System.Disk and power on the IIGS.

2) When the Finder desktop appears, insert the blank disk and initialize it. Call it "AppleShare".

3) Launch the Installer from System.Tools. If you have two drives, eject the System.Disk. If you have one drive, eject the System.Tools disk.

4) Insert the blank "AppleShare" disk you just initialized and click the "Disk" button until its name appears.

5) Select the installer script entitled "AppleShare on 3.5 Disk" and click Install. Before installing, the system will display an alert message explaining not to install this on your only copy of the system disk. Click "Perform This Update" to continue. Some disk swapping will be required.

6) When the installation is complete, make sure the AppleShare startup disk you just created is in drive 1, and restart. To save time, you can hold down the Control Open-Apple Reset keys rather than quitting to the Finder and doing a Shutdown.

7) When the Finder desktop is on the screen, use the mouse to select the graphic Control Panel under the Apple menu. If it isn't already highlighted, click on AppleShare.

8) Select the file server and connect using the Administrator name and password. Then select the AppleShare File Server volume and mount it. Close the graphic Control Panel.

9) Run the Installer on System.Tools. Click the "Disk" button until the file server name appears -- in our example, "A2".

Here is how to install some files over the network onto the file server volume:

1) Select the following scripts: Server Network Startup, Server Quick Logoff and optional scripts.

For optional scripts, select anything that IIGS systems staring over the network will require. For instance, if you need access to a network printer, like a LaserWriter or an AppleTalk ImageWriter, install those scripts.

2) Select the optional scripts you need by holding down the Open Apple key when you click on them.

Caution: do not try to install "Latest System Files" or "Latest System Files (No Finder)", or IIGS users will not be able to start up over the network. Note: There was an error in the original version of this article that indicated you should install the "Latest System Files (No Finder)" script. It was corrected in a subsequent issue of "TechBeat."

When you click "Install", the system installs the IIGS system software over the network. To show network activities, double arrows at the top left of the screen will flash. The installation may take some time.

3) Before you run off to grab a coffee, wait for the alert message telling you to "install this update only on a file server's startup volume". Click "Perform This Update" to continue.

4) When the installation is complete, hold down the Control Open-Apple Escape keys to enter the text Control Panel.

5) Under Slots, set the startup slot to 7. The next time you start up the IIGS, it will be over the network. First, however, you have to set up the server for IIGS users. See section 4 below.

4. Setting up the File Server for IIGS Users

Follow these steps:

1) Leaving the file server running, get into the AppleShare Admin program.

2) Use the Shift-click method to highlight all the IIGS users you want to start up over the network.

3) Select "Set Startup" under the Apple II menu.

4) To have IIGS users start up into the Finder, select "Finder" under the System folder. You can also select a default network printer if one is available, and if you installed the drivers for them in section 3. Note that any printers to be selected must be powered up and visible over the network.

For Apple IIe users, you can set the startup application to be any ProDOS 8 application (file type SYS). Apple IIe systems that will start up over the network must be equipped with AppleShare Workstation cards and 128K of RAM. They must also be enhanced. (If you will be running Aristotle Admin, you'll need an Apple II Memory Expansion card with at least 256K of RAM. IIGS users who want to run Aristotle Admin need to define a RAM disk with 256K of RAM.) IIGS users can also start up to any ProDOS 8, ProDOS-16, or GS/OS application.

When you have finished setting up the startup information for your Apple II users, all that remains is setting the access privileges:

1) Under the "Volumes" menu, select "Volume List", double-click on the server volume, and a dialog box will be displayed.

2) Set the access privileges so that everyone can "See Files, See Folders", and apply changes to all enclosed folders, unless you have an existing server.

In such a case, you should not apply changes to enclosed folders, as there may be folders you do not want IIGS users to have access to. IIGS users need "See Files, See Folders" access to the top level of the server startup volume, the System Folder, and all folders within it. They will also need the same access to the Icons folder, which holds IIGS Finder icons. Users may experience errors if they don't have sufficient access for various operations. If you find some IIGS software that needs write access to a particular folder, you should lock that folder so that adventurous users can't throw it away.

3) When you are finished setting up access privileges, quit from the AppleShare Admin program.

5. Booting over the Network

You should now be able to start up over the network with a IIGS or a IIe. A IIGS starting up over the network displays several different screens during the startup process. You can verify you installed the correct version of the Apple II Setup on your file server by watching the "Starting up over

the network" screen. It should say "2.1.3 GS.OS" at the top right if you used version 2.1.3, which comes with IIGS System 5.0.4.

After a few moments, the system prompts the user for a user name or allow guest access, if it is enabled. Be sure to test server logon as a normal user, and not just as the Administrator. That way you can uncover any access privilege problems. If you ever see an error message, take note of any error codes and compare them to the list in the back of the "ProDOS Technical Reference Manual" or in the "Apple IIGS GS/OS Reference." Two of the most common errors are listed in the Appendix at the end of this article. You'll find that most errors are easily explainable unless you mixed up software versions during installation.

You have now completed the installation of software to allow IIGS and IIe users to start up over the network.

Appendix: Common Errors

Cannot load file Start.GS.OS
Error = $0046
This is the message you get if you failed to follow Step 3 correctly. It is a ProDOS file system error $46, which means "Path not found". The GS/OS files the system requires to start up could not be found on the file server. If you have multiple file-server volumes, verify you installed the IIGS System Software over the network onto the server startup volume.

Unable to load descriptors
Error was $004E
This message denotes an access privileges problem. It is a ProDOS file system $4E error. This means the user had insufficient access privileges to complete the required operation, or, possibly, the file was locked. Most likely, you haven't given the user who experienced the error "See Files, See Folders" access to the top level of the server startup volume, the System folder, and all folders within it.

Macintosh LC, IIe Card: "Printer Port already in use" Message

Why do I get a "Printer Port is already in use" message when starting up the Apple IIe Card application program?

This article has been archived and is no longer updated by Apple.
This message comes up when the Macintosh is trying to use the Printer Port for a LocalTalk (network) connection and the Apple IIe card is trying to use the port for serial data. This resulting conflict causes the "Printer Port is already in use" message.

If you are connected to a LocalTalk network in the Printer Port, use the "Network Printer" icon and not the "Printer Port" icon in the Slots menu. See the manual for information on selecting the network printer.

If you are connected to a serial printer in the Macintosh printer port, return to the Macintosh Chooser and select "AppleTalk Inactive". This removes the conflict, and the port-in-use message will no longer appear when you start the IIe application.

TA46466_Apple_IIe_Card_Joystick_Support_(TIL07875).pdf

Apple IIe Card: Joystick Support

Does the Apple IIe Card support 16-pin joysticks or annunciators?

This article has been archived and is no longer updated by Apple.
No, the card supports only the 9-pin joystick/paddle connector.

Published Date: Feb 18, 2012

Apple IIe Card: Memory Card Only Supports 1 MB

With the Apple IIe Card, can the memory card support more than 1MB?

This article has been archived and is no longer updated by Apple.
To avoid compatibility problems, the memory card supports only 1MB, even if the Macintosh LC has more memory.

Published Date: Feb 18, 2012

Apple IIe Card: No Support for Parallel Printers

Can you print to parallel printers with the Apple IIe Card?

This article has been archived and is no longer updated by Apple.
No, the card supports only the ImageWriter and LaserWriter printers.

Published Date: Feb 18, 2012

Apple IIe Card: Troubleshooting Apple IIe Applications

If an Apple IIe application doesn't seem to work properly on the Apple IIe Card, see the troubleshooting procedures in this article.

This article has been archived and is no longer updated by Apple.

Changing General Option Panel Settings:
---
* If text is hard to read, use monochrome monitor or switch to monochrome mode on a color display. Text is hard to read, because of the higher resolution of Mac monitor.

* If an application won't boot, when set to Fast speed, run at it at Normal speed.

* If an application seems slow, run it at Fast speed to get best performance.

* On some applications, do not turn Type Ahead "On". Program will lock up when you start to type.

* On some applications, if the Auxiliary Memory is turned on, the Memory Expansion card is ignored, even if it is installed in a slot. Do not turn on Auxilliary Memory, unless the application asks for it.

How to Change Slot Settings in the Option Panel

Change them one at a time in the following order:

1) If the application won't boot, the program seems to hang, or garbage appears on screen, remove the clock card.

2) If the application won't boot, the program seems to hang, or garbage appears on screen, remove the memory card.

3) If the application won't boot, the program seems to hang, or garbage appears on screen, remove all unnecessary cards.

4) If the application is still not working, study the configuration of the Apple IIe that the program is currently running on. Then, set up the Apple IIe Card's slots so that they are the same as those in the actual Apple IIe.

5) Some applications can only print directly to an ImageWriter with the printer icon only in slots 1 and 2.

6) Some applications can only print directly to ImageWriter with printer icon only in slot 1.

Changing SmartPort Settings in the Option Panel

Due to copy protection, some 3.5-inch application disks must be booted from the external UniDisk Drive (white 3.5-inch drive). Make the external drive, slot 5 drive 1.

Hardware Configurations
---
1) Some programs have mouse and joystick conflict. This also happens on the Apple IIe computer. To use the mouse, remove the joystick. Otherwise, the mouse will appear erratic.

2) With some programs, it is better to use the keyboard or joystick control, because the mouse is very sensitive. (The same thing happens

less apparently on the Apple IIe.)

3) Some programs must use two 5.25-inch disk drives. This is not a problem; you just need two 5.25-inch disk drives (the Apple 5.25-inch Drive, which is the only Grey drive).

Problems That Cannot Be Overcome
---

* An application tries to access Apple-IIe-specific hardware (due to copy protection or poor code). Generally, these programs won't work on the Apple IIGS either.

* An application does not print to a serial printer, only a parallel printer, and there is no parallel port on the LC. (Possibly a serial-to-parallel converter would work, but we did not test this).

* If the application uses special cards that are not available in the Slot Settings, the program will not work.

In general, rules that apply to an Apple IIe application running on the IIe are still in effect on the Apple IIe Card. If the application requires the KeyCaps to be down, the KeyCaps must be down. If DOS 3.3 must first be loaded, DOS 3.3 must be loaded first.

ImageWriter II: Carriage Motor Makes a Loud Humming Noise

This article has been archived and is no longer updated by Apple.

BEFORE YOU START: Familiarize yourself with the ImageWriter II Technical Procedures. Be sure to follow proper ESD procedures.

PROBLEM: The carriage motor makes a loud "humming" noise when the carriage moves to the left side of the printer upon power up. This sometimes occurs after the printer has been taken apart and reassembled.

CURE: Check to make sure the ground strap from the CPU board to the Driver PCB is NOT routed around the right side of the motor mount. If the ground strap gets between the motor mount and the carriage assembly, the left carriage position sensor never detects the carriage, consequently the motor stays on as the printer tries to complete the power up sequence. The ground strap should be positioned between the motor mount and the left side of the case. If the ground strap is routed correctly see the General Troubleshooting Procedures for the ImageWriter II.

TA46471_Apple_IIGS_System_Fan__(TIL07890).pdf

Apple IIGS: System Fan (2/97)

Why does the Apple IIGS need a fan?

This article has been archived and is no longer updated by Apple.

If your Apple IIGS has three or more expansion cards, they can cause a noticeable buildup of heat inside the computer. The Apple IIGS System Fan maintains the proper internal case temperature under these conditions, prolonging the life of your computer's components.

This fan is not compatible with the Apple IIGS Upgrade for Apple IIe computers.

Super Serial Card: Description (12/96)

This article describes the Super Serial Interface Card.

This article has been archived and is no longer updated by Apple.

Overview

The Apple II Super Serial Card provides a configurable RS 232 interface, allowing an Apple II, Apple II Plus, or Apple IIe computer to exchange data with other computers, modems, printers, terminals, and accessories employing a bidirectional RS-232-C interface in serial format (one bit at a time).

The Super Serial Card features an on-board switch allowing the operation of a printer, modem, or other serial device. This switch also eliminates the need for special connection cables such as modem eliminators.

System Requirements

To use the Apple II Super Serial Card, you need:
* an Apple II, Apple II Plus, or Apple IIe computer system with an available expansion slot; and
* a printer, modem, or other serial device.

Technical Specifications
---
* Single Level: EIA RS-232-C
* Connector Type: DB-25 socket
* On-Board ROM: 2K x 8 bit (2316 or equivalent)
* ACIA: S6551 or equivalent
* Baud Rate Selection: via on-board DIP switches (default) or via software commands
* Data word format: 1 start bit, 1 or 2 stop bits, 7 or 8 data bits; odd, even, or no parity
* Available baud rates: 50, 79, 110, 134.6, 150, 300, 600, 1200, 1800, 2400, 3400, 9600, 19200
* RS-232-C Signals Supported: RTS (Request to Send), CTS (Clear to Send), DTR (Data Terminal Ready), DSR (Data Set Ready), DCD (Data Carrier Detect), RXD (Receive Data), TXD (Transmit Data), (SG) Signal Ground.

Internal Cable Pinout
---
10 Pin Connector	25 Pin Connector	Signal Name
pin 1	pin 1	Frame Ground
pin 2	pin 2	Transmit Data
pin 3	pin 3	Receive Data
pin 4	pin 4	Request to Send (RTS)
pin 5	pin 5	Clear to Send (CTS)
pin 6	pin 6	Data Set Ready (DSR)
pin 7	pin 19	Secondary CTS
pin 8	pin 7	Signal Ground
pin 9	pin 20	Data Terminal Ready
pin 10	pin 8	Data Carrier Detect

Pin Explanation

FRAME GROUND: Provides electrical connection to give both devices connected a common frame ground. Usually tied to Signal Ground inside the cabinet of one of the devices.

TRANSMIT DATA: This pin conveys serial data sent from the Super Serial card. This is one of the pins that may need to be crossed over if the peripheral device is a DTE. The MODEM/TERM plug can perform this crossover.

RECEIVE DATA: This pin receives serial data sent from the device the Super Serial card connects the computer to. This is one of the pins that may need to be crossed over if the peripheral device is a DTE. The MODEM/TERM plug can perform this crossover.

REQUEST TO SEND (RTS): This signal is used by the computer to ask the peripheral device if it is ready to receive computer data. Often a device such as a printer will ignore this signal (will not have a pin connected to it) because the signals primary use is to control half duplex modems.

CLEAR TO SEND (CTS): This pin receives the peripheral's ready to receive data response to an RTS from the computer. Again this pin is used most often by modems.

DATA SET READY (DSR): This pin receives the signal generated by the peripheral that indicates that the peripheral is turned on and ready to communicate. This is one of the pins that may need to be crossed over if the peripheral device is a DTE. The MODEM/TERM plug can perform this crossover.

SECONDARY CTS: Some modems can transmit and receive on two channels (that is two separate communications on the same line). The Secondary CTS pin would be used to receive the peripheral's ready to receive data response to an RTS for the second channel from the computer.

SIGNAL GROUND: When this pin is connected between two RS232 devices it provides a common electrical level that the devices can reference the RS232 signals to.

DATA TERMINAL READY: This pin becomes active when the computer and SSC are ready to go on line. This is one of the pins that may need to be crossed over if the peripheral device is a DTE. The MODEM/TERM plug can perform this crossover. Also this pin can be used for flow control protocol handshaking.

DATA CARRIER DETECT: This pin receives the signal generated by a modem when it senses a carrier on the telephone line. The SSC would then respond by telling the computer that data was going to be coming from the modem.

Jumper Block

The jumper block has two positions, Terminal and Modem. The jumper block eliminates the need for special connection cables such as modem eliminators.

Switches

The fourteen switches, split into two banks named SW1 and SW2, are diagonally opposite the slot contacts. Holding the card so that the switches are at the top left, the two banks are arranged like this:

SW1 1 2 3 4 5 6 7 SW2 1 2 3 4 5 6 7
ON ON
OFF OFF

The markings SW1, SW2, ON, and OFF may not appear exactly as shown. If the lever on a switch is pointing towards the top of the card, the switch's contact is closed and the switch is ON. Use a sharp but soft point, like a pencil point, to move the levers.

Switch 1
1 2 3 4
Baud Rate:
50 On On On Off
75 On On Off On
110 On On Off Off
135 On Off On On
150 On Off On Off
300 On Off Off On
600 On Off Off Off
1200 Off On On On
1800 Off On On Off

2400 Off On Off On
3600 Off On Off Off
4800 Off Off On On
7200 Off Off On Off
9600 Off Off Off On
19200 Off Off Off Off

Switch 2
5 6
Auto linefeed after CR:
Enabled On
Disabled Off
Passage of interrupts from ACIA to CPU:
Enabled On
Disabled Off

Mode Switches

The setting of the Mode switches (SW1 5 and 6) determines the function of the remaining switches in one of two modes, Communications mode or Printer Mode. Printer Mode includes two modes for printer PROM emulation.

Switch 1
5 6
Mode:
Communications On On
Printer Off On
SIC P8 Emulation On Off
SIC P8A Emulation Off Off

Communications Mode

The remaining switches have the following functions:

Switches SW1-7 and SW2-7
SW1 7 SW2 7
Protocol:
RS-232C On Off

Switches SW2-1, SW2-2, SW2-3, SW2-4
SW2 1 2 3 4
Data format:
8 data/1 stop On On
7 data/1 stop On Off
8 data/2 stop Off On
7 data/2 stop Off Off

Parity:
None N/A On
Odd On Off
Even Off Off

Printer and Printer PROM Emulation Mode

The remaining switches have the following functions:

Switches SW1-7 and SW2-7
SW1 7 SW2 7
Protocol:
Normal Clear to Send (RS-232C) On Off
Secondary Clear to Send Off On

Switches SW2-1, SW2-2, SW2-3, SW2-4
SW2 1 2 3 4
Data format:
8 data/1 stop On
8 data/2 stop Off
Delay after carriage return:
32 milliseconds On
None Off
Line Width (Printer mode has no parity):
40 On On
72 On Off
80 On Off
132 Off Off

Important Information

There is a problem with using the Super Serial Card (SSC) terminal firmware at 1200 baud on an unenhanced IIe. The IIe 80-column card can't keep up with the data stream and eventually loses characters. Avoid this problem with faster, more sophisticated programs that can handle interrupts, such as Access II or third party terminal software. The proper terminal software also will allow use of the Extended Text Card with a modem at 1200 baud.

X Windows for A/UX: Where To Get "xmh" (9/94)

Article Last Reviewed: 13 September 1994

Where I can get a copy of xmh? It is part of the MIT X11R4 Windows distribution, but I have noticed that this item is absent from Apple's X Windows for A/UX product.

This article has been archived and is no longer updated by Apple.
As you may have noticed from the "Getting started with X Window System for A/UX" documentation, only the "display server" and "xstdcmap" client applications are from X11R4. Other client applications, such as the programmer libraries and the X toolkit, are still from X11R3. Since "xmh" is from X11R4 client applications, it is not included in our current release of X Window System for A/UX.

Apple's "X Window System 2.1 for A/UX" product includes xman, but not xmh.
xmh requires the "mh" mail handling tools that are not included in either
X11 or A/UX.

To locate xmh, connect to ftp.uu.net on the internet.

A/UX 2.0: AT&T LP Spooler and Macintosh IIfx IOP Problem

On a Macintosh IIfx the "cancel" command under the AT&T Line Printer spooler system can't gracefully shut off the child process of "lpsched". Therefore, the remaining entries in the printer queue can't be printed. Eventually, this hangs the printer port (on a direct connected ImageWriter II). The problem only happens on the Macintosh IIfx. We suspect the problem is on the A/UX 2.0 Macintosh IIfx IOP serial driver tty settings.

This article has been archived and is no longer updated by Apple.

As a workaround, the "Macintosh IIfx Serial Switch" Macintosh OS CDEV seems to work for A/UX 2.0, which lets Macintosh IIfx serial ports be set to be Macintosh IIfx IOP-"compatible" for applications that use printer or modem ports that don't operate properly.

Apple IIc (Platinum): Mouse Moved from Slot 4 to Slot 7

When the latest ("platinum") version of the Apple IIc was released, the main circuit board was changed to accommodate the new Memory Expansion Card. The firmware was also changed: the logical location for the mouse was moved from slot 4 (where the memory card image now resides) to slot 7.

This article has been archived and is no longer updated by Apple.

This causes problems when customers run the sample BASIC program in Appendix A of the AppleMouse II User's Manual. To make the program work correctly with the newest Apple IIc, change all occurrences of [slot] 4 to [slot] 7.

Macintosh Portable: Set Internal SCSI Drive to ID "0"

Why does the Macintosh Portable internal hard drive need to be set to SCSI address "0"?

This article has been archived and is no longer updated by Apple.
If the Macintosh Portable internal hard drive is set to a SCSI address other than "0", the Portable CDEV does not operate properly. The hard drive starts up, but the Portable CDEV does not display the "Minutes Until Automatic Sleep" option for the hard drive, and the function is disabled. This is like starting up the Macintosh Portable with no internal hard drive.

Jumpers E1, E2, and E3 on the Conner drives are used to set the SCSI address. They use a binary counting system with E1 the least significant bit. No jumpers across E1, E2, and E3 (the factory setting) sets the drive to SCSI address "0", which is the standard Conner SCSI ID system.

DRAM: General Information

Article Change History

09/11/92 - REVIEWED
* For technical accuracy.

1) What information is stored in DRAM?

2) What happens to the information in DRAM when the Macintosh is turned off?

3) Is DRAM volatile?

This article has been archived and is no longer updated by Apple.

1) DRAM is the memory used by the Macintosh to temporarily hold the information or data that the user is working on until it is saved to a hard disk, floppy disk, or another storage medium.

2) Once power is no longer supplied to RAM, the contents is lost. If a user is working on a Macintosh and turns the system off without saving the work, what was in DRAM during the work session will be lost. The data lost is the data that the user was working on before the power was removed.

3) Yes, DRAM is volatile. That's the nature of DRAM (Dynamic Random Access Memory); it needs to be constantly powered with electricity to remember its contents. The same applies to SRAM (Static Random Access Memory); however, SRAM does not need to be refreshed the way DRAM does, and this provides data retention for extended periods, which is why this type of RAM is used in Macintosh Portable computers.

TA46481_LisaCalc_Problems_with_rounding_(TIL00791).pdf

LisaCalc: Problems with rounding

This article has been archived and is no longer updated by Apple.
In cell A2, enter the formula INT(A1*100)/100; in cell A1, enter the value 1.17. You would expect the result in A2 to be 1.17; however, due to difficulties in converting decimal to binary and back, the result returned is 1.16. If the intent of the above expression is to round to two decimal places, then use ROUND(A1,2) or ROUND(INT(A1*100)/100,2). To compare the two cells to see if they are equal, use IF(A2-A1<.0001,EQUAL,NOTEQUAL).

Apple Ethernet NB Card: Power Consumption

How much current does the Apple Ethernet NB Card draw?

This article has been archived and is no longer updated by Apple.

The Apple Ethernet NB Card draws 3.96 watts at 5 volts. The recommended wattage limit for each NuBus slot is 13.9 watts.

The overall power-draw audit of the Ethernet NB Card (including power consumed by an external AAUI transceiver) is 1.165A.

AAUI cabling should not exceed 1.5m.

Apple IIe: Brother EM-701 Typewriter Interface

This article has been archived and is no longer updated by Apple.

Here's how to interface a Brother EM-701 typewriter to an Apple IIe with a Super Serial Card. This information was supplied by Merlin's Computers, Covina, California.

Brother EM-701 Switch Settings

SW-1-1 ON
1-2 OFF
1-3 ON
1-4 OFF
1-5 OFF
1-6 OFF
1-7 OFF
1-8 ON

SW-2-1 OFF
2-2 OFF These set the typewriter to 9600 baud.
2-3 OFF
2-4 OFF

SW-2 Controls the baud rate of the typewriter. If the typewriter is set to 8-bit transmission, the typewriter will need a different print wheel because of the $ and %. The characters don't appear in the 8-bit form or have problems printing.

Super Serial Card

(The Super Serial Card needs to have the jumper block pointing toward 'Terminal').

SW-1-1 OFF
1-2 OFF
1-3 OFF
1-4 ON
1-5 ON
1-6 ON
1-7 ON

SW-2-1 ON
2-2 OFF
2-3 OFF
2-4 OFF
2-5 ON
2-6 ON
2-7 OFF

Macintosh IIfx: 4MB SIMM Configuration (11/94)

I have a Macintosh IIfx with 4MB of RAM and a Macintosh Display Card 8*24 GC installed. When I add the 8*24 GC CDEV to the System Folder and try to start up the system, it hangs at the "Welcome to Macintosh" message. When I remove the 8*24 GC CDEV from the System Folder, the system starts up and operates normally. (This does not happen with a Macintosh IIfx with 8MB of RAM installed.)

This article has been archived and is no longer updated by Apple.
This problem is peculiar to the Macintosh IIfx with 4MB of RAM installed. Apple states that, when using only 4MB of RAM in the Macintosh IIfx, the SIMMs MUST BE installed in bank A. Although the Macintosh IIfx may work normally in some configurations with the SIMMs installed in bank B; in others, it doesn't.

To eliminate the problems you are experiencing with the Macintosh IIfx, make sure the RAM SIMMs are in bank A.

StyleWriter: HyperCard 2.X Card Printing Problem/Fix (12/94)

Vertical lines do not align perfectly when printing to a StyleWriter from HyperCard 2.X using the "Print Card" option. This problems does not happen with horizontal lines or when using the "Print Stack" option.

Is this a known problem?

This article has been archived and is no longer updated by Apple.
Yes, StyleWriter output has vertical-line registration problems when using the "Print Card" option in HyperCard 2.X.

Claris is aware of the issue and is investigating it. The registration problem is caused by the HyperCard printing code, not by the StyleWriter.

The registration problem can be avoided by using the "Mark Card" option:

1) Go to the card you want to print.

2) Display the "message box".

3) Type "Mark Card" into the message box and press either the Return or Enter key. Note that more than one card can be marked at a time.

4) Select "Print Stack" from the "File" menu.

5) Select the "Marked Cards" option.

6) Click the "Print" button.

7) Type "unMark Card" in the message box and press either the Return or Enter key. This unmarks the card so it doesn't printed the next time this procedure is used.

StyleWriter: How to Avoid Paper Jams

Have there been any reported paper-jamming problems with the StyleWriter printers?

This article has been archived and is no longer updated by Apple.
We haven't received any reports of paper-jamming problems with the StyleWriter printers.

The StyleWriter has a detachable cut-sheet feeder that easily connects to the printer. When the sheet feeder is connected properly, the product performs flawlessly. When attaching the sheet feeder, ensure that the sheet feeder is locked in place and that the paper support is installed; it's also important to press the release button on the sheet feeder to snap the paper panel forward for proper positioning. The sheet feeder holds up to 50 sheets of 20-pound paper and automatically feeds the paper while printing.

The StyleWriter can be used without the sheet feeder with front or rear manual feed. The front and rear manual-feed options simplify the printing of single-sheet paper, envelopes, labels, and transparencies.

Paper-Feed Features
---
* Detachable cut-sheet feeder accurately feeds up to 50 sheets automatically.
* Rear manual-feed slot is ideal for printing materials like envelopes, labels, transparencies, and heavy paper.
* Front manual-feed slot provides easy access for standard paper.

System 7: Memory Errors in PrintMonitor

Article Change History

09/17/92 - UPDATED
* With information about System 7 Tune-Up.
05/11/92 - REVIEWED
* For accuracy.

When trying to print in the background, PrintMonitor delivered the following message: "Not enough memory to print. PrintMonitor will try to print again when more memory is available." The document was saved in the PrintMonitor queue and never printed.

I've encountered this problem on Macintosh II and Macintosh SE computers with 2MB to 8MB of RAM installed. I turned off virtual memory. I printed from various applications, including the Finder.

This article has been archived and is no longer updated by Apple.

In low-memory situations this is a valid error message; for instance, if PrintMonitor needs more memory allocated to it, or if there is not enough available RAM to launch PrintMonitor. But if the suggested memory size for PrintMonitor is adequate, and there is plenty of RAM for PrintMonitor to expand, this error message indicates there is a problem with the PrintMonitor application.

When trying to print in the background under System 7, a "Not enough memory" error might indicate a damaged PrintMonitor application. When this occurs, install a new copy of PrintMonitor from the Install 1 disk. Either install this file using the Installer program, or simply drag it over. The waiting print jobs will print as soon as you install the new PrintMonitor.

You may also want to run Disk First Aid, but this isn't always necessary. To avoid this kind of damage to PrintMonitor in the future, upgrade your system software with the System 7 Tune-Up. Revised LaserWriter drivers in the Tune-Up prevent PrintMonitor from getting damaged as it occasionally did before. The current version of System 7 Tune-Up is 1.1.1.

System 7: Intercharacter Spacing, Kerning in 6.x and 7.0

Is there any difference between intercharacter spacing and kerning pairs in system software 7.0 and 6.x? What is the difference between bitmap and TrueType spacing?

This article has been archived and is no longer updated by Apple.

```
Spacing and Kerning
-------------------
Apple didn't change spacing with the bitmap characters in System 7, but
matched each bitmapped character width in 6.x to the corresponding
character in 7.0.  New bitmap characters created just for System 7 will
have spacing differences.

Apple didn't changed the kerning pairs either.  Many applications allow you
to change kerning.

Bitmap and TrueType Spacing Differences
---------------------------------------
Bitmaps use integer widths, while outline fonts (TrueType) use fractional
widths.  Fractional widths allow exact size adjustments for intercharacter
spacing as well as kerning.  Integer widths limit these adjustments to
whole sizes.  This is one of the main advantages of TrueType.
```

System 7: Reserved Fonts are Invisible

I was moving fonts between my System 6 and System 7 Macintosh computers. I didn't see some of the basic fonts, like Geneva 9 or Chicago 12, on my System 7 Macintosh. When I moved the same suitcases back to System 6, I saw them with no problem using Font/DA Mover. Why?

This article has been archived and is no longer updated by Apple.

In System 7.0, reserved fonts such as Geneva 9 or Chicago 12 are made invisible by the Finder. This prevents novice users from removing these fonts from the System suitcase, which would cause crashes. Reserved fonts are invisible in both System font suitcases and regular font suitcases under System 7.

Reserved fonts include:

* Geneva 9
* Geneva 12
* Chicago 12
* Monaco 9

Although this prevents serious damage to system files, it is confusing to users who moved the fonts using Font/DA Mover under System 6.

Font/DA Mover can view and copy these fonts. Remember that Font/DA Mover version 4.1 is necessary to use suitcases that contain TrueType fonts.

System 7: Problem with Stationery‘s "Save In" Option

Article Change History

08/19/92 - REVIEWED
* For technical accuracy.

The Finder seems to restart itself or crash occasionally when I try to save a copy of a stationery document. This happens when I double-click the document in the Finder and attempt to save the copy to a floppy disk.

This article has been archived and is no longer updated by Apple.

There is a known problem with the Save In option of stationery documents created from older "stationery-unaware" applications.

The problem occurs after you double-click on a stationery document, choose Save In, and then insert a floppy disk. When you choose to save the document on the floppy disk, you will either get an error or the system will return to the Finder without saving the document.

The problem does not occur when you mount a floppy disk before you open the stationery document.

GS BASIC: Features and Editing Commands

This article discusses GS BASIC features and editing commands.
This article has been archived and is no longer updated by Apple.

ToolBox Primitives

GS BASIC includes primitives (built-in, low-level commands) that let the user interact with the ToolBox routines. Whereas most other ToolBox routines are implemented in external libraries that need to be explicitly called up, these commands -- Eventdef, Menudef, and Taskpoll -- are included in GS BASIC itself because they bind the ToolBox and BASIC line numbers.

Eventdef

The structure of Macintosh-like programs, as implemented by the Apple II GS and its ToolBox routines, requires that programs be event-driven. This means that the heart of a program is a main loop that constantly monitors what events -- mouse clicks, keyboard presses, window update events, network activity, and so on -- have taken place. Eventdef associates BASIC line numbers with these events: whenever one of these events occurs, GS BASIC starts running the instructions specified in a table set up by the programmer and maintained by Eventdef.

Menudef

One of the places a mouse click can occur is in the menu bar. When this happens, a menu is displayed, letting the user select a menu item. The user specifies that a certain function is to be performed. Like Eventdef, Menudef associates BASIC line numbers with menu items, so that when a menu item is selected, GS BASIC can easily determine what statements to run, and run them.

Taskpoll

Programs shouldn't start fielding events and responding to them until all the ToolBox libraries are loaded and the tables that Menudef and Eventdef maintain are initialized. The Taskpoll command lets the programmer turn off the interrupting feature of GS BASIC and turn them on when ready for them.

Procedures and Functions

The most convenient structure of of any program is a procedure, function, or subroutine. In most BASICs, including Applesoft, subroutines are implemented in a very straightforward fashion. GS BASIC provides a more powerful way to specify and call procedures.

Applesoft lets programmers call subroutines with the GOSUB xxx command, where xxx is the line number to which control branches. Statements are then executed until a RETURN command is executed, at which time the program returns to the line that called the subroutines, and continues from there.

GS BASIC allows programmers to define specific procedures that are called with the PROC command. The PROC command performs the same functions as Applesoft's GOSUB, and lets the programmer pass local parameters as well.

GS BASIC has a more powerful line editor than Applesoft's. Access it by typing EDIT linnum[-linnum]

Editing Commands

CONTROL-D	delete character to the left of cursor; moves line to left
CONTROL-F	delete character under the cursor; moves line left
CONTROL-X	delete entire line
CONTROL-Y	delete line to left and under cursor
CONTROL-E	toggle insert mode
RETURN	accept entire line (even characters to right of cursor)
DELETE	same as CONTROL-D

System 7: CloseView‘s Command Keys

I was trying to open a folder in System 7, when suddenly a big black box appeared around my pointer. I can make it go away if I turn off extensions at startup (by holding down the Shift key), but I don't understand what's going on.
This article has been archived and is no longer updated by Apple.
You have inadvertently activated CloseView, a utility designed to aid the visually impaired. To turn off CloseView, type Command-Option-O. To learn how to use CloseView, refer to the Macintosh User's Guide.

When using CloseView, notice that its shortcut keystrokes are very similar to shortcut keystrokes built into the new Finder. When trying to open the folder, you may have inadvertently used the keystroke to activate CloseView. In general, the slight differences between the Finder and CloseView commands may cause confusion.

For example:

```
Finder:     Command-O                Opens window
CloseView:  Command-Option-O         Turn on/off CloseView

Finder:     Command-X                Cut
CloseView:  Command-Option-X         Turn on/off magnification

Finder:     Command-UpArrow          Go to next higher level
CloseView:  Command-Option-UpArrow   Increase magnification
                                    level

Finder:     Command-DownArrow        Go to next lower level
                                    (open icon)

CloseView:  Command-Option-DownArrow  Decrease magnification level
```

It is unlikely that a novice or casual user would stumble across CloseView, because it is never installed by the System 7 Installer (not even by Easy Install). In fact, if a pre-System 7 version of CloseView was in the System Folder, the System 7 Installer deletes it. To install CloseView, drag it into the Control Panels folder or the System Folder.

CloseView was designed for the visually impaired who may not be able to see their keyboard. A mis-keyed command could cause them a great deal of confusion.

CloseView does not display zoom effects when windows open or close. For many people, the zoom effects are useful for visual orientation, showing what the computer is activating or putting away. Without the zoom effects, items just appear and disappear from the screen.

Note: CloseView is written as a single word, not as Close View.

System 7: Finder Doesn‘t Allow Renaming Fonts

I'm using System 7, and I'm trying to rename some fonts in the Finder, but it won't let me. I can rename any of my sounds, but none of my fonts.
This article has been archived and is no longer updated by Apple.
You can't change the names of bitmap or TrueType fonts in the System 7 Finder.

There are a few legitimate reasons why end users would want to rename their fonts, but allowing that freedom in the Finder would cause most users considerable confusion. Specifically, if a font name changes, you have to manually update all instances of that font in documents. For instance, if you changed "Palatino" to "MyFont," you would have to open any documents that used "Palatino," select the text, and choose "MyFont" from the font menu. Likewise, transferring files with renamed fonts between Macintosh computers would generate many problems. Therefore, System 7 does not allow changing font names in the Finder.

Utilities such as ResEdit and many font design applications can change the names of fonts.

Warning: The instructions in this article refer to using ResEdit. Apple Computer, Inc., is not liable for any damage done to your software through the use of ResEdit to alter software.

Macintosh Plus: Effects of Extreme Cold

What are the long-term effects of storing a Macintosh Plus in extreme cold (-40 degrees) for an extended period?

This article has been archived and is no longer updated by Apple.
Here are the operational and non-operational (storage) condition specifications for the Macintosh Plus:

Temperature

Degrees Degrees
Fahrenheit Celsius
--- ---
Operating 50 to 104 10 to 40
Storing -40 to 122 -40 to 50

Humidity

All conditions: 5% to 90% relative humidity

Altitude
---
0 to 4615 meters
0 to 15,000 feet

If you expect the Macintosh Plus to be at -40 (F or C) for a long period, especially if there are occasional dips significantly below -40 degrees, you may encounter some, all, or none of these conditions:

- Possible thermal stress of the electrolytic capacitors to the extent that they crack, leak, or fail when thawed.

- Possible thermal stress of the fiberglass/epoxy resin of the circuit boards, leading to hairline fractures of the printed circuit board.

- Possible thermal stress of the CRT, leading to hairline fractures of the glass.

- Possible thermal stress of the cables inside the Macintosh Plus, leading to hairline fractures of the insulation or conductor.

- Possible thermal stress of the junctions inside the integrated circuits caused by the variation in thermal expansion of the plastic case and the metal wires.

Any of these scenarios can lead to failure of one or more parts of the system. We recommend that you keep the Macintosh Plus in a closet or in some other heated living quarters. If this is not an option, after removing the system from this extreme temperature, allow the Macintosh Plus to return to a normal operating temperature slowly, possibly over a period of days. By allowing the components to warm gradually, if there hasn't been any irreversible damage, the system should be fine.

If the capacitors have cracked, you may notice some fluid dripping down the left side of the case or some discoloration in this area. In that case, or if the system behaves erratically or you hear crackling or popping on startup, shut down the system immediately and take it to your authorized service center for examination.

AppleShare PC: "Needs Version 3.1 or Later of DOS" Message

When loading AppleShare PC to an IBM PC, a customer is getting this error message: "needs version 3.1 or later of DOS". The customer tried DOS versions 4.0 and 5.0 and got the same message.

This article has been archived and is no longer updated by Apple.
The problem is associated with the REDIR subdirectory file located in the AppleShare PC DIR. In all probability, your customer is using an AppleShare PC version older than 2.X, which works effectively only with DOS versions through the 3.X series. Your customer needs to upgrade to the more current Farallon version of the AppleShare PC software.

This error message also has been reported by customers when they haven't properly followed the directions for loading files for DOS 5.0. The customer should pay close attention to the instructions regarding "expanding" (see the DOS 5.0 User's Manual, page 28).

MacX25: Multiple Workstation Support

How many workstations does the MacPAD software (shipped with MacX25) support?

This article has been archived and is no longer updated by Apple.

If each workstation uses only one virtual circuit, 64 workstations can access the MacX25 server simultaneously. However, applications can be written so that multiple circuits can be accessed by one workstation; therefore, the number of workstations that can be supported depends on how the application is written.

Personal LaserWriter: How To Determine Page Count

Can you determine the page count on the Personal LaserWriter LS?

This article has been archived and is no longer updated by Apple.
There is no way to determine the actual number of pages that have been printed on a Personal LaserWriter LS and Personal LaserWriter SC controller board or print engine. The Personal LaserWriter NT controller board stores the number of pages that the controller board has printed, but not the number of pages the engine has printed.

With the Personal LaserWriter NT, the customer can keep track of the page count using the controller board (user test print). If the controller board is never changed, the page count should be accurate. If the board is repaired or replaced, the page count will change, and it is the customer's responsibility to monitor the printer's page count. Since the Personal LaserWriter LS and Personal LaserWriter SC do not have the controller count capability, the customer needs to keep track of the page count. To assist customers with this task, Apple offers the Repair Log Label (part number 826-0481).

GS BASIC: General Description

This article gives a general overview of GS BASIC and the differences between it and Applesoft BASIC.

This article has been archived and is no longer updated by Apple.

GS BASIC vs Applesoft BASIC

Unlike Applesoft BASIC, GS BASIC gives programmers access to all of the new features of the Apple IIGS: Super hi-res graphics, the Ensoniq sound chip, expanded memory, the new Tools, and other enhanced ROM facilities.

GS BASIC is an entirely RAM-based language. It does not rely on Applesoft, nor is it related to it in any way except that they are both BASIC languages. In fact, because of advanced features like access to all of GS RAM, more powerful I/O instructions, and access of external routines, GS BASIC is not 100% compatible with Applesoft. The number of commands is increased from 120 to over 200 (see List of GS BASIC Commands), many Applesoft BASIC commands do different things in GS BASIC, and some Applesoft commands do not appear in GS BASIC at all (PR#, IN#, and HGR for example). Applesoft and GS BASIC files are stored differently on disk, and are not interchangeable. Finally, GS BASIC is designed to run under ProDOS 16, whereas Applesoft can run only under ProDOS 8. Otherwise, GS BASIC would not be able to take advantage of the GS's powerful new features.

GS BASIC gives the programmer twice the number of variable types that Applesoft has. In addition to Integer, Real, and String types, GS BASIC provides Double Real, Double Integer, and Long Integer.

GS BASIC is not as fast as Applesoft. Applesoft runs the following program in 4 seconds, while GS BASIC takes 43 seconds:

```
10 FOR i = 1 TO 10000
60 NEXT i
```

With longer programs, the difference is less. This program takes Applesoft 48 seconds and GS BASIC 217 seconds:

```
10 FOR i = 1 TO 10000
20 a=i-i
30 a=i+i
40 a=i/i
50 a=i*i
60 NEXT i
```

Access to External Routines

One of GS BASIC's main advantages is its powerful library and external routine facilities. Provided with GA BASIC are many ToolBox Definition Routines (TDFs) that let programmers call the GS's ToolBox routines (QuickDraw II, Menu Manager, Window Manager, Sound Manager, and so on). These routines are setup with the LIBRARY command, and called with the CALL and EXFN commands.

Programmers can also define and call their own library routines. These are loaded with the INVOKE command, and called with the PERFORM and EXFN commands.

Display Format

GS BASIC offers improved formatting of listings. Users can specify how much space appears between a line number and the first statement, and how far to indent when listing program statements within a FOR...NEXT or DO...WHILE...UNTIL loop. See the List of Built-in Constants and Reserved Variables.

Sound

Sound is created through Sound Manager routines.

Built-in Constants and Variables

GS BASIC includes pi calculated to 20 digits. Also, GS BASIC stores many system parameters in reserved variables. Much of the system's status can be determined and changed by examining and setting these variables. For example, the cursor's screen position is stored in the variables VPOS and HPOS. You can move the cursor simply by assigning new values to these variables.

Labels

GOTO, GOSUB, and ON xxx commands can point to labels instead of line numbers, making programs much easier to follow.

Instead of: 1234 GOSUB 50: REM Read a character from the modem

the programmer can type: 1234 GOSUB READ_MODEM

Looping

GS BASIC includes three looping structures not in Applesoft:

IF...THEN...ELSE
FOR...NEXT...STEP
DO...WHILE...UNTIL

These structures, common in other languages such as Pascal and Fortran, give the programmer greater flexibility in program control. In addition, the IF...THEN structure has multi-line capabilities. This means that all statements that appear between the IF and the THEN do not have to appear on the same line.

PRINT USING and INPUT USING
PRINT USING and INPUT USING have long been a features of BASICs other than Applesoft. GS BASIC implements them with a vengeance, making them nearly as powerful as FORTRAN format statements. A programmer has many ways to specify how to print data to a screen and read it from a keyboard or other device.

When defining a USING statement, a programmer can specify it in many ways. The first way is to specify the format on the same line, right after the USING statement. The second way is to assign the formatting string to a variable (such as FMT$), and then enter that variable after the USING statement. This allows the programmer to use the same formatting in many PRINT statements. Or, if the programmer doesn't want to use variable space to store a formatting string, he can use the IMAGE command to define it. The programmer can then simply refer to the line on which it appears in the PRINT USING statement. All of these options apply to INPUT USING as well.

PRINT and and INPUT USING don't merely have to work with the text screen. With optional device extensions, a programmer can PRINT or INPUT to or from a file, or PRINT to a printer or even the Super-Hi-res graphics screen.

Finally, GS BASIC offers many formatting commands that are to be placed in the formatting strings. These are divided into three groups: String Spec, Literal Spec, and Numeric Spec. Numeric Spec is further divided into three sub-sections: FIXSPEC, SCISPEC, and ENGRSPEC. The SCALE command can be used to accurately reposition a decimal point in a floating point number.

Macintosh Portable: Caps Lock Function and System Sleep

The Macintosh Portable loses the Caps Lock key function when reactivated from the "sleep" mode.

This article has been archived and is no longer updated by Apple.
In the following situation, the Caps Lock key function is lost:

1) The Caps Lock key is pressed and locked in the down position.
2) The Macintosh Portable is put into the "sleep" mode.
3) The Macintosh Portable is reactivated by pressing a key.

Even though the Caps Lock key is still locked in the down position, the system reverts to lowercase. This happens because the "Caps Lock flag" stored in the register is temporary and is lost during the sleep mode.

To reinstate Caps Lock after reactivating the Macintosh Portable from the "sleep" mode, press the Caps Lock key twice: once to unlock it and a second time to reset it.

This applies to both the original Macintosh Portable and the revised Macintosh Portable with the backlit screen. No "fix" is expected. This problem does not exist with the PowerBooks.

System 7: Importing and Saving Documents with Excel 3.0

Excel 3.0 does not seem to be saving changes under System 7.

This article has been archived and is no longer updated by Apple.

Under System 7, if you open an Excel 2.2 document or text file with Excel 3.0, then Save, the Save dialog box opens automatically to the folder where the Excel application resides. According to Microsoft, this is a feature because the file is "new" (converted). The original document, in a different folder, is not overwritten.

If you later open the original document, you might think your changes were never saved.

Here are two workarounds:

- Before saving, navigate back to the original folder and replace the old file.

- Keep Excel 3.0 and your Excel documents in the same folder.

TA46539_System_Installer_on_Printing_Tools_Disk_is_for_System__(TIL07985).pdf

System 7: Installer on Printing Tools Disk is for System 6

Article Change History

09/14/92 - REVIEWED
* For technical accuracy.

I removed my printer drivers from the Extensions folder and deleted them. When I reinstalled the system software, the Printing disk displayed this message: "The selected disk 'Hard Disk' does not require a printer update." However, when I chose Customize and "Software for LaserWriter" it installed the proper driver. Is the Installer confused?

This article has been archived and is no longer updated by Apple.

If the PrintMonitor is in the Extensions folder, the Installer on the Printing disk will indicate that you don't need to update. The Installer on the Install 1 disk will allow you to install a specific driver using Customize. Remove the PrintMonitor to do an Easy Install.

There's a good reason for this. The Installer on the Printing Tools disk is for System 6. The preferred method is to use Customize from the Installer on the Install 1 disk.

System 7: Problem Printing AP Newswire Maps

Article Change History

09/21/92 - REVIEWED
* For technical accuracy.

I installed system software 7.0 on one Macintosh in a network. I then updated the printer drivers of the other Macintosh computers, which are running system software 6.0.3, to the system 7.0 printer drivers. All the computers are getting PostScript Errors "Error: Limit Check, offending command: Closed Path" when printing from MacDraw II version 1.1. The documents are maps in MacDraw II that come from the AP Newswire via Satellite.

This article has been archived and is no longer updated by Apple.

Once you have eliminated all system-related software conflicts, we suspect System 7 drivers and Postscript are creating this conflict.

According to Claris Tech support, this is a known issue with AP Newswire maps. The objects in these documents have too many vertices. They must be simplified by removing vertex points using MacDraw II. The System 7 LaserWriter drivers are less tolerant of this problem than the System 6 drivers.

Workarounds:

* Do not print these documents running System 7 or the System 7 printer drivers, or

* Simplify them with MacDraw II.

TA46541_System_Virtual_Memory_Page_Size_(TIL07988).pdf

System 7: Virtual Memory Page Size

Article Change History

08/17/92 - REVIEWED
* For technical accuracy.

What is the page size for virtual memory and the largest swap of memory at one time?

This article has been archived and is no longer updated by Apple.

The page size is 4K for virtual memory. In other words, with virtual memory turned on, System 7 will read and write memory to disk in 4K chunks.

The largest amount of RAM swapped to or from disk at one time is one megabytes.

Published Date: Feb 18, 2012

System 7: When the Finder Loses Its Colors

My colors sometimes disappear in the Finder. Especially my desktop patterns, labels, and window frame colors. Also, my general control panel colors sometimes switch to black and white. Why is this?
This article has been archived and is no longer updated by Apple.
When an application, INIT or control panel "takes away" colors from the Finder, the Finder tries to replace the colors. Unfortunately, the Finder is not "intelligent" about this. A "used" color is no longer available to the Finder. This is very noticeable in 4-bit mode, 16 colors. When the Finder doesn't have enough choices, it often defaults to black and white
until the colors are "given back."

Restarting the computer is one of the actions that restores the colors. It may also be necessary to restore the
label colors to their original values. Search on label colors for more information.
Published Date: Feb 18, 2012

Macintosh Mouse: Mouse/Cursor Tracking

This article has been archived and is no longer updated by Apple.
There is a way to detect if the mouse was moved and how far it was moved. The mouse location call provides the current coordinates of the mouse position. If two successive calls to mouse location yield different results, then the mouse has moved, and (given the previous and present coordinates) the distance traveled can be calculated. If you wish to know the total distance the mouse traveled between calls to mouse location, then you should use the mouse odometer. The fact that the mouse moves is not considered an event, so it is up to the programmer to determine the mouse's location and distance traveled. Also note that the only thing that happens to a cursor as it travels around the screen (without any mouse clicks) is that the cursor changes according the area it is in--e.g., it becomes an I-beam over text, a cross in a spreadsheet, and an arrow most other times. It should also be noted that these cursor changes are under program control and are not automatic.

Here is a small program that uses some of the cursor/mouse tracking routines. These routines automatically keep the cursor on the screen--i.e., if the cursor is already at the left edge of the screen and you move the mouse further left, the cursor stays on the screen. This program is similar to the Hendrix program on the MacMaster 2 disk in that it makes noise.

```
PROGRAM VOL;
USES

System 7: Three-D Desktop Background Patterns

Article Change History

09/11/92 - REVISED
* For clarity.

How do I get those neat background patterns that I see advertised with System 7?

This article has been archived and is no longer updated by Apple.

If you install System 7 over another system, you won't see the new patterns. This is because System 7 saves the old patterns over the new desktop patterns when you install over the old system. Install System 7 on a clean drive (a drive from which you have removed the System Folder) to see the new patterns.

For larger images and patterns, look for shareware or commercial utilities like Wallpaper which provide this capability.

Published Date: Feb 18, 2012

System 7: How Apple PostScript Printers Handle TrueType

With what Apple PostScript printers will TrueType work?
This article has been archived and is no longer updated by Apple.
First, a little history on TrueType and PostScript:

The TrueType format places all PostScript devices into one of three class categories depending on the device and its TrueType capabilities. The three classes are:

1) Class A devices are those with a TrueType scaler embedded in the PostScript device (the ROM.) For example, the LaserWriter IIf/IIg, LaserWriter Pro 600/630, and the LaserWriter Select 360 all fall into this category.

2) Class B devices are those that depend on the TrueType scaler to be downloaded to the device separately from the font itself. Most third-party 680x0 PostScript printers and the LaserWriter Pro 810 fall into this category.

3) Class C devices do not have TrueType available in any form.

Here's how TrueType works with Apple LaserWriter Printers:

LaserWriter
The original LaserWriter, containing a 68000 microprocessor, can't print TrueType. The TrueType rasterizer CANNOT be downloaded to the original LaserWriter which has ROM version 1.0 (PostScript version 23.0). Thus, it CANNOT print TrueType fonts. The TrueType rasterizer can only be downloaded to LaserWriters with PostScript version 38.0 or ABOVE. PostScript version 38.0 or 47.0 ROMs are LaserWriter Plus ROMs which can be installed on an original LaserWriter, making it a LaserWriter Plus.

In terms of which LaserWriter driver to use, version 6.1 or greater is required to print TrueType.

LaserWriter Plus
The LaserWriter Plus, also 68000-based, does not download the scaler code, but TrueType will work. It converts TrueType code to encrypted Type 3 instructions (better known as unhinted Type 1) before delivering it to the printer. Performance is slow due to memory management constraints in that version of ROM. Memory constraints affect performance when converting and downloading large numbers of TrueType fonts.

LaserWriter IINT
The LaserWriter IINT, also 68000-based, downloads the scaler code and TrueType does work. The performance and handling of multiple fonts is faster than the previous printers but slower than the LaserWriter IINTX.

LaserWriter IINTX and IINTX-J (Kanji version)
The LaserWriter IINTX and IINTX-J, which contain a 68020 microprocessor, download the scaler code and TrueType does work. Performance and handling with multiple fonts is faster than with the earlier printers. How much faster depends on the RAM available size.

Personal LaserWriter NTR
The TrueType Scaler is in ROM for optimum TrueType font performance.

LaserWriter IIf & IIg
The TrueType Scaler is in ROM for optimum TrueType font performance.

LaserWriter Select 310
The LaserWriter Select 310 downloads the scaler code and TrueType does work.

LaserWriter Pro 600 & 630
The TrueType Scaler is in ROM for optimum TrueType font performance.

LaserWriter Select 360
The TrueType Scaler is in ROM for optimum TrueType font performance.

LaserWriter Pro 810
The LaserWriter Pro 810 supports TrueType using the downloaded scaler.

System 7: TrueType and the Original LaserWriter

Article Change History

05/13/93 - REVISED
* For technical accuracy

When I try to print to an original LaserWriter using the TrueType fonts under System 7.0, I get a PostScript error, but Adobe Fonts print fine.

This article has been archived and is no longer updated by Apple.

The bottom line is that the TrueType rasterizer CANNOT be downloaded to the original LaserWriter which has ROM version 1.0 (PostScript version 23.0). Thus, it CANNOT print TrueType fonts. The TrueType rasterizer can only be downloaded to LaserWriters with PostScript version 38.0 or ABOVE. PostScript version 38.0 or 47.0 ROMs are LaserWriter Plus ROMs which can be installed on an original LaserWriter, making it a LaserWriter Plus.

In terms of which LaserWriter driver to use, version 6.1 or greater is required to print TrueType.

Published Date: Feb 18, 2012

System 7: Lost Microsoft Word Custom Icons Fix

Under System 7, whenever I save a Microsoft Word file with a custom icon, the icon becomes the generic document icon. Also, the comments in the Get Info box disappear.
This article has been archived and is no longer updated by Apple.
Microsoft Word is one of the few programs that completely rewrites an existing document when it saves, rather than updating the original. This deletes the custom icon and the Get Info comments from the file. But the file is still marked to use a custom icon, and the Finder deals with this by assigning it the generic document icon.

To fix the icon, use ResEdit or another resource utility to reset the "Use custom icon" bit to off. Pasting in a custom icon will not fix the problem; you will get the error message "The command could not be completed because an error of type -39 occurred."

Here is a workaround for Word files saved in normal format (this doesn't work for Word text files):

1) In Microsoft Word, choose Commands from the Edit menu.
2) Choose Fast Save Enabled, and click Add.
3) Save the change, replacing the current Word Settings.
4) Cancel out of the Commands window.
5) Under MS Word's Edit Menu, make sure Fast Save Enabled has a check next to it.
6) You should now be able to change the document without losing the custom icon.

Warning: The use of ResEdit is not recommended for anyone unfamiliar with its use. Irreparable damage to your software is possible, always work from a backup. If you are unfamiliar with its use, do not use it.
Published Date: Feb 18, 2012

System 7: When Finder Icons Seem to be Stacked On One Another

Article Change History

09/10/92 - REVIEWED
* For technical accuracy.

I use file sharing to make a folder available to a co-worker. When I open the folder and view by icon, I see only one document because all the icons in the folder are stacked on top of each other.

This article has been archived and is no longer updated by Apple.

This is not a bug, and there is no difference in the way Finder handles icons for file sharing. With the "Always snap to grid" feature turned on in the Views control panel, it is possible for icons to share the same place on the grid. This feature allows more items to fit in a window. If you prefer not to stack icons, you can turn off the "snap to grid" feature.

Here's how to "unstack" the icons:

1) Choose "by Icon" or "by Small Icon" from the View menu.

2) Hold down the Option key while choosing Clean Up by Name from the Special menu.

We were able to duplicate icon stacking when we dropped the documents one-by-one into an open folder at approximately the same location with snap to grid turned on. The result was the same with either straight or staggered grid. Icon stacking does not happen when moving documents to closed folders.

Published Date: Feb 18, 2012

System 7: Switching Among Keyboard Maps

I installed multiple keyboard maps into the System file to allow switching between languages like English and Spanish.

Here are two ways I switch maps:
- Open the Keyboard control panel and select it from a list, or
- Press a Command-Option-Spacebar sequence to "rotate" between the maps.

The issue is some applications use the Command-Option-Spacebar sequence for other operations. If I use this sequence to perform the application's command, the command is performed as expected, but the operating system also "rotates" the keyboard maps. Is there a workaround?
This article has been archived and is no longer updated by Apple.
This key sequence is a reserved part of the operating system which should not be used by an application. Applications may also use this key sequence for other operations but there will be conflicts if multiple keyboard maps are present.

Here are three workarounds:
- Don't install more than one keyboard map into the System if you can avoid it. System 7.5 installs all keyboard maps as a default. You can remove those you will not be using by opening up the System suitcase and dragging them to the trash.

- After using the key sequence, open the Keyboard CDEV and change the map with the mouse.

- Use the mouse to perform the application's command, rather than the key sequence.

A checkbox will be added to the Keyboard Control Panel to disable this feature in System Update 1.0 for System 7.5.

Daisy Wheel Printer: Problem with random marks in printed output

This article has been archived and is no longer updated by Apple.
When random ticks, accents and so on show up in the printed output of a daisy wheel printer, there are two probable causes:

1. The printwheel is bad. If the spokes of a printwheel were either poorly manufactured or subsequently bent, then the hammer may strike two spokes at a time. If the same letters are always printing poorly, then it is likely that the printwheel is at fault.

2. The stepper motor and the hub where the printwheel mounts are out of sync. To check this, print vertical lines using the vertical bar character and horizontal lines using the underscore character. If the characters are not vertical or horizontal and the lines are broken, then the alignment is off.

System 7: Disk Space for Minimal and System-Specific Installs

What is the difference in disk space required for a Minimal Install ("Minimal Install for...") and a System Specific Install ("System Software for...")?
This article has been archived and is no longer updated by Apple.
We installed system software 7.0 on several Macintosh computers to answer this question. For the minimal installs, we chose Customize and then "Minimal Install for..." For the system specific installs, we chose Customize and then installed software configurations for the specific Macintosh.

System software requires about 1593K, averaging Minimal Installs and Full Installs together.

A minimal install placed the following items in the System Folder of a Macintosh SE/30:

Name	Type	Size
Apple Menu Items	(folder)	--
Control Panels (alias)	(file)	2K
Control Panels	(folder)	--
Finder	(file)	356K
System	(file)	756K

There are no Extension or Preference folders. The system builds them at startup. The only font that you can see is the Geneva (Italic) 9 used for alias filenames.

Here is a table of differences in disk space needed for Minimal Installs and System Specific Installs (SSI):

Computer	SSI	Minimal	Difference
Macintosh Plus	2496	975	1521
Macintosh SE	2499	974	1525
Macintosh Classic	2508	974	1534
Macintosh SE/30	2737	1116	1621
Macintosh LC	2670	1049	1621
Macintosh Portable	2541	971	1570
Macintosh II	2737	1116	1621
Macintosh IIx	2737	1116	1621
Macintosh IIsi	2669	1049	1621
Macintosh IIcx	2737	1116	1621
Macintosh IIci	2666	1045	1621
Macintosh IIfx	2671	1050	1621

System 7: Compatibility of E-Machines Products

What are the System 7-compatible versions of the E-Machines monitor driver software?
This article has been archived and is no longer updated by Apple.
Here are the versions of E-Machines monitor driver software required for System 7:

* For the 8-bit cards: version 3.0.2 or later.
* For the 24-bit accelerated cards: version 3.2 or later.

The only known compatibility issue is with E-Machines' 17-inch Big Picture monitor. After you choose Shutdown, it displays a restart screen.

System 7: MacPlot Driver Configuration

I cannot print to my Hewlett Packard plotter from MacDraw Pro. Why?
This article has been archived and is no longer updated by Apple.
The MacPlot driver for the Hewlett Packard plotter must be configured in a particular way under System 7. According to Microspot's technical support, this is the setup:

1. Put the driver in the Extensions folder.
2. Select the plotter in the Chooser.
3. Pull the driver out of the Extensions folder to the top level of the System Folder.
4. Configure the plotter through the Configure Application.
5. Put the driver back into the Extensions folder.
6. Make an alias of the driver and place it at the top level of the System Folder.

The driver is bundled with MacDraw Pro and is also sold separately by Microspot. If the driver was bundled with a Claris product, please call Claris for technical support instead of Microspot.

System 7: Purpose of Cerulean Data File

I do not know if I installed system software 7.0 correctly. What is this Cerulean Data file on the Install 2 disk, and why didn't the Installer put it on my hard disk?

This article has been archived and is no longer updated by Apple.

The System file is so large that it can't fit on a single 800K floppy disk. To distribute it on 800K floppy disks, many of the resources that are part of the System file are in the Cerulean Data file. The Installer combines the System and Cerulean Data files into a single System file on your hard disk. The Installer displays the message, "Building file: System" when it is joining the files on the hard disk.

The resources stored in the Cerulean Data file include icons, desktop patterns, instructions for displaying menus, dialog boxes and alert messages, and other code to make the system work. Because the Installer adds all of these items to the System file, you don't need a copy of the Cerulean Data file on your hard disk.

System 7: Compatibility Checker Stack and Newer Applications

I just got the latest version of an application that the developer assures me is System 7-compatible. But when I ran the Compatibility Checker, it flagged the application as incompatible and told me I needed an update. What's going on?
This article has been archived and is no longer updated by Apple.
The Compatibility Checker version 1.0 was compiled from information sent to Apple by developers before the release of System 7. Since then, many developers have released newer versions of their software. Because the Compatibility Checker looks at specific version numbers of applications, it cannot recognize the newer versions, and flags them as incompatible.

If you have questions, contact the application developer for a definitive answer, including compatibility regarding file sharing, 32-bit addressing, and virtual memory.

Note: Even when application developers state explicitly that their products are System 7-compatible, there is no guarantee that those applications are problem-free; issues still may occur when other variables are brought in such as third party INITs and cdevs, also known as system extensions and control panel devices.

Compatibility Checker 1.1, which updates the original, has 165 new records, as well as updated product compatibility information and corrected phone numbers. It also offers compatibility information on third-party drivers. But with new versions of applications coming out constantly, the same situation may be encountered as with the original version.

System 7: Role of Font/DA Mover 4.1

In the System 7 Group Upgrade Kit, there's a copy of Font/DA Mover 4.1, but no instructions for using it. The only reference to it is on page 64 of the "Group Upgrade Guide," which says that it isn't compatible with System 7. Why did Apple include it on the CD?
This article has been archived and is no longer updated by Apple.

Using with System 7

Font/DA Mover 4.1 is **compatible** with System 7, although you do not need to use Font/DA Mover to manipulate fonts in the System file and other suitcases directly in the Finder. However, the Font/DA Mover 4.1 is necessary to use with System 7 if you want to manipulate/add/delete fonts **within** a specific application such as MusicProse or Finale! by Coda Music.

It is also possible to use Font/DA Mover with System 7 to recover fonts from a damaged System file, but Apple does not recommend or support this use of the Font/DA Mover.

Using with System 6

Font/DA Mover 4.1, along with the TrueType extension, is included on the System 7 CD-ROM so customers can use TrueType fonts on Macintosh computers running System 6. Font/DA Mover 4.1 allows System 6 users to manipulate TrueType fonts (view, copy, and remove) in their System file and other suitcases, in addition to bitmap fonts and desk accessories. It is otherwise identical to earlier versions of Font/DA Mover.

The TrueType extension (INIT) allows System 6 users to create, display and print documents that use TrueType fonts. It's fully compatible with system software 6.0.7 and 6.0.8. It may also work with version 6.0.5, but Apple hasn't fully tested it, and doesn't support this use of it.

System 7: Restoring From HD Backup

How do I restore a backup of my hard disk that I made with HD Backup if I've installed System 7? I heard that HD Backup is incompatible with System 7.
This article has been archived and is no longer updated by Apple.
HD Backup is incompatible with System 7, but there are a number of workarounds if you need to restore an HD Backup set of data onto a volume.

Workaround One
You can start up from a volume that has System 6 on it, such as a second hard disk or floppy disk. This works even if you have only a single floppy drive and no extra hard disk (although you'll be swapping floppy disks a lot). To start from the other drive, insert a System 6 floppy disk before startup, or choose the other hard disk using the Startup Disk control panel.

Workaround Two
Another workaround is to pull individual files from floppy disks in the backup set onto the hard disk. This works best if there are a few files that need to be restored, but not the entire backup set. You may have difficulty if HD Backup split large files across multiple floppy disks.

Workaround Three
The most drastic workaround is to reinstall System 6 on the hard disk and then run HD Backup. Note that this may be a problematic procedure in itself, and the details of that procedure aren't covered in this article. Specifically, most new Macintosh models require System 7 to operate and would not be able to move back down to System 6.

System 7: Precautions When Installing Over System 6

Be careful when installing System 7 over any version of System 6, especially versions earlier than 6.0.5. This article tells you the steps to take and the precautions to observe when installing System 7 over System 6.
This article has been archived and is no longer updated by Apple.

Step One

Be sure to search the entire hard disk for multiple system folders, and remove all but the main System Folder.

Use the Find File DA in System 6 to find multiple system folders. Note that you may have to do this a number of times. If there are multiple system folders, Throw away any extras and empty the Trash.

Important Note: Altering a System Folder by renaming it and removing the Finder does not work with versions earlier than 6.0.5; the Macintosh may crash or hang on startup.

Step Two

Run the Compatibility Checker.

Step Three

There are two ways to proceed in this step:

Install System 7 over System 6. To do this, simply start up from the Install 1 disk and run the Installer program.

Alternatively, trash the remaining System and Finder files, rename the System Folder, and install System 7. Use this procedure if you've had problems installing over System 6. The Installer won't move any of the System 6 files into the new System Folder. You can manually move some files from the old System Folder, such as INITs, cdevs, fonts, and application Preference files or folders. Unknown or untested software may conflict.

System 7: Using the "Before You Install" Stack

The menus don't seem to work in the Before You Install HyperCard stack. I get messages telling me to click on an arrow when I make a selection.
This article has been archived and is no longer updated by Apple.
The stack named "Before You Install" demonstrates the features of System 7 in a HyperCard window that greatly resembles the real system, but is only a demonstration program. Items that you would normally select with the mouse such as menus, icons, or windows, are just pictures, and are not actually interactive. If you try to use the mouse to select any items on screen, you get the following message: "This example desktop is for System 7 demonstration only. To move ahead in any topic, click the forward arrow, below."

The program displays the current topic at the lower left of the HyperCard window. On the lower right are buttons to help navigate through the stack (left and right arrows, Contents and/or Topics). If you can't see these items at the bottom of the window, it may be that the window is too low on your screen. You can't reposition this HyperCard window when it doesn't have a title bar.

To reposition the window, quit HyperCard (type Command-Q), and again launch the Before You Install stack. The title bar, "Before You Install System 7," should now appear at the top of the window. Use the mouse to reposition the window properly so that you can see "Contents" (the topic name) and the Quit button at the bottom of the window.

One other thing you may find is that Before You Install has no close box or button, only a Quit button. Since it is possible to have more than one HyperCard stack open with HyperCard versions later than 2.0, quitting will close all open HyperCard stacks.

The sample applications mentioned in Before You Install, such as MemoWriter and Let's Draw, are fictional and are not included with System 7 or HyperCard.

A/UX: No Yellow Pages for Non-Privileged Accounts

The Yellow Pages appears to be broken, at least on a non-privileged account. When I try to log in, login fails with several error messages written to the screen. These are quickly erased before returning to the login screen.
This article has been archived and is no longer updated by Apple.
The situation is that non-privileged accounts cannot log in. Root can still log in. This isn't a Yellow Pages issue; it's a disk space issue.

The default file system for A/UX is a Berkeley file system. The Berkeley file system reserves a percentage of the disk for use exclusively by root. The default "high water mark" is 10 percent, although you can adjust this with the tunefs command.

If the unused space on the file system is less than the high water mark, non-privileged users cannot log in. This is to prevent situations where you cannot do anything because the disk is too full. Root can still login and remove files to enable other logins.
Published Date: Feb 18, 2012

Printing: Background Printing Is Normally Slower

Documents printed with non-TrueType screen fonts under background printing take several minutes per page on the Personal LaserWriter LS. Why?

This article has been archived and is no longer updated by Apple.

This is normal. The advantage of background printing is that it lets you work on a task while a document is printing. Printing in the background means that printing must share the processor with some other process instead of taking all the processing speed. Therefore, it is slower. What you see is normal.

DAL 1.2: Simultaneous Users Require Unique UICs

Only one user can use DAL at a time. When someone else tries to connect, the message "could not find ADSP server" appears. We are using AppleTalk for VMS 3.0 and DAL 1.2.

This article has been archived and is no longer updated by Apple.

Give each user an individual account. Without a unique UIC, the second connect attempt fails.

Published Date: Feb 18, 2012

DAL: When RDB Locks Entire Database

When I use DAL to insert data into RDB, the whole system locks until the user doing the insert does a commit. It should only lock the current record, not the entire database.
This article has been archived and is no longer updated by Apple.
When using DAL with RDB, each user should have a distinct VMS account, including unique UICs and login directories. With a DBMS like Oracle, which has its own user account validation system with the DBMS, you don't need distinct VMS accounts.

However, RDB relies on VMS to let it know who is using which record. If RDB can't distinguish between the different accounts, it can't tell which record is being updated, so it locks all records opened by the current user. Because, in this case, everyone is effectively the same user, all records are locked for everyone until the commit is complete.

This issue was addressed in RDB 4.0 and DAL 1.3.

LisaTerminal 7/7: Configuring Preferences to Use a Modem

This article has been archived and is no longer updated by Apple.

To use a modem from LisaTerminal 7/7, use Preferences to make the device connection a Serial Cable rather than a Modem. If you fail to do this, the system will constantly set LisaTerminal communications to Off-Line.

Published Date: Feb 18, 2012

AppleWorks 1.1: Scribe Printer Indentation Issues

When I print from AppleWorks 1.1 to my Scribe printer the second paragraph always prints with the wrong indentation. Why does this happen?
This article has been archived and is no longer updated by Apple.
When you print an AppleWorks 1.1 file using the Scribe printer, the first paragraph always prints with an indentation of 5 spaces, as it should. If, however, the second paragraph prints without the proper indentation, check to see whether justification is set to FULL JUSTIFY. If not, set the justification to FULL JUSTIFY and then try again.

This problem has been corrected in later versions of AppleWorks.
Published Date: Feb 18, 2012

DAL and MVS/TSO Server: Troubleshooting Tips

If the login sequence seems to work, but attempts to open tables and retrieve data fails, try these troubleshooting steps.
This article has been archived and is no longer updated by Apple.
From the Begin prompt with the DAL Tester or DAL Debugger, enter the command:

```
describe DBMS;
printall;
go
```

If DB2 isn't listed as a choice, then something is wrong with the DAL installation on the host. If DB2 is listed as an available DBMS, then try to open it with:

```
open DB2 DBMS;
go
```

If the DBMS opens successfully, then try:

```
describe databases;
printall;
go
```

A list of available subsystem IDs should appear. If nothing comes back, then the environment file is emplty or inaccessible.

Next, open the desired database and see what's in it with:

```
open db2 database '_____';
describe tables;
printall;
go
```

If the only tables listed are not correct, or if a -551 error is returned, see Appendix B of the "Data Access Language Server Installation and Operating Guide for MVS/TSO." Appendix B describes how to set up views for DAL users to access the DB2 tables.
Published Date: Feb 18, 2012

DAL 1.2: DB-2 Query With Sum Statement Crashes Server

This DB2 query crashes the DAL server on the mainframe:

select column1, sum(column2) from table group by column1;

Without the sum statement, the query works without any problems. The same query works fine in native DB2 SQL.
This article has been archived and is no longer updated by Apple.
This is a known bug in DAL 1.2. It's fixed in DAL 1.3.

A sum fails in DAL 1.2 if the column to be summed is of type 9 (VARCHAR) with nulls allowed. It doesn't matter if there actually are nulls in the table or not.

DAL 1.1: Large Amounts of Data Kill Processes

I have a DAL application that sends large amounts of data down the network and often kills the DAL server process, while it's running.
This article has been archived and is no longer updated by Apple.
That's a known problem with DAL 1.1. This is fixed in version 1.2.
Published Date: Feb 18, 2012

DAL: Insert Command Blocks Other Users

I am using DAL, using the same account name as other users in my group. When one user does an insert, no one else can do anything (no selects, for example) until that person finishes the insert and does a commit.

This article has been archived and is no longer updated by Apple.

Because all of the users are using the same account name, the system freezes until someone finished the insert command. To ensure data integrity, DAL locks the database until the command is completed. The only solution is to provide each user with a unique account.

Published Date: Feb 18, 2012

AppleWorks 2.0: New way to create Mail Merge documents

AppleWorks 2.0 lets you merge database records with word processor documents to create mail merge documents using a new print option which can be imbedded in a word processor file.
This article has been archived and is no longer updated by Apple.
Follow these steps:

1. From the database, create a table style report.

2. The records appear on the clipboard in the order of the last sort in the table style report. Open your word processor document.

3. In your word processor document, place the cursor where the mail merge category should go. Press the Open-Apple-O keys to bring up the printer options, then select "MM". A list of Mail Merge catagories appears.

4. Select a database category. Answer the question regarding whether a line should be deleted if the category is blank.

5. Repeat steps 3 and 4 until all the categories you want are placed in the document.

Mail Merge places the database category in the document with a provision for appending one space at the end of the merged entry. A caret also appears in front of the category name. AppleWorks marks this caret as a mail merge printing option; place the cursor on this caret and the prompt line reads "Mail Merge".

6. Press Open-Apple-P to print the word processor document.

7. If there is mail merge data in the document, AppleWorks will ask you if you want to print the document with the categories merged, or un-merged (as you see it on the screen.)

8. If there isn't mail merge data on the clipboard, AppleWorks tells you. Be further aware that only during printing does AppleWorks report an error if the word processor document has a category name that AppleWorks cannot find on the clipboard.

System 7: Troubleshooting Compatibility Checker Problems

This article tells what to do if the Compatibility Checker will not launch, or if it fails before completing the check. Also included is a table with the correct versions of HyperCard to use with various system software versions.
This article has been archived and is no longer updated by Apple.

Procedures for System Software 6.0.5 or Later

- System 6.0.5 requires HyperCard 1.2.5 or higher; make sure you have the right version.

- Start from the System 7 Disk Tools disk and run Disk First Aid, then try Compatibility Checker again.

- Copy the HyperCard application and Home stack from the System 7 HyperCard disk and the Compatibility Checker stack from the "Before You Install" disk to your hard drive. Now try running the Compatibility Checker from the hard drive.

- If the Compatibility Checker still won't launch, there may be a problem with the current System 6 software. Start up with the System 6 System Tools disk or the version 6.0.7 System Startup disk and install the operating system with Installer.

- Back up your hard disk, start from the Install 1 disk and install System 7 first. After the installation is complete, restart the computer with the shift key down to temporarily disable all system extensions.

Procedures for System Software 6.0.4 or Earlier

- Make sure you are using the correct version of HyperCard. See the Operating System/HyperCard Requirements section of this article to find the HyperCard version you need.

- You must upgrade to System 7 before using the Compatibility Checker if:

* You don't have the correct version of HyperCard on your hard disk and can't locate it on a floppy disk.

* You are using a version of the system software earlier than 4.1.

There are more instructions for this procedure on page 11 of the "How to Install System 7" manual, included with System 7. After the installation, restart the computer while pressing the shift key to temporarily disable all system extensions.

Operating System/HyperCard Requirements

System Version	Recommended HyperCard Versions
7.0	2.1 or later
6.0.5 - 6.0.7	1.2.5, 2.0 or later
6.0.4	1.2.5
4.1 - 6.0.3	1.2.2
Prior to 4.1	n/a

For information about Compatibility Checker error messages, search under "System 7" and "Compatibility Checker".
Published Date: Feb 18, 2012

System 7.x: Compatibility Checker Error Messages

This article tells you what to do when the Compatibility Checker displays these error messages.
This article has been archived and is no longer updated by Apple.
Since the Compatibility Checker was made into an application with version 2.0, which comes with System Software 7.1, and it's newer version 7.1.1, which comes with System 7 Pro, you no longer receive HyperCard error messages.

If you are using the HyperCard based Compatibility Checker that comes with System 7.0, the following information lists common error messages.

Error: "New file format requires a new version of HyperCard."

After you convert the Compatibility Checker stack to HyperCard 2.0 format, you **cannot** run it under earlier versions of HyperCard. This converted stack needs system software 6.0.5 or later, and HyperCard 2.0 or later. If you do not have the required software, follow these steps:

1. Copy the HyperCard application and Home stack from the System 7 "HyperCard" disk, and the Compatibility Checker from the "Before You Install" disk to your hard disk.
2. Start the Macintosh with the System 7 "Disk Tools" disk.
3. Double click on the Compatibility Checker. Because the Compatibility Checker can check for compatible INITs and CDEVs only in the System Folder of the startup disk, it won't check the System Folder on your hard disk. But you can still check the applications on your hard disk.

Error: "This stack has not been converted. It must be converted before it can be modified."

Manually copy the Compatibility Checker stack to the hard disk before launching it.

Error: "You need an additional 193K of space on 'Before You Install System 7:Compatibility Checker 1.0' to use Compatibility Checker"

The Compatibility Checker displays this message when running from an unlocked floppy disk. The only option is to quit, lock the floppy disk, and try again.

System 7: Corrupted Suitcase and/or System File

I have a corrupted suitcase and/or System file. How can I retrieve my fonts or sounds?
This article has been archived and is no longer updated by Apple.
Unfortunately, we have no recommended fix. While we don't recommend it, as a last resort you may want to take the following steps:

1. Start from the Disk Tools disk.
2. Open the System Folder on your hard disk.
3. Rename your System file.
4. Throw the Finder in the Trash.
5. Empty the Trash.
6. Reinstall system software 7.0.
7. Restart from the hard disk.
8. Open the renamed System file with Font/DA mover 4.1, holding down the Option key.
9. Resave the fonts and sounds into new suitcases.
10. One by one, open up the fonts in System 7 by double-clicking on the suitcase, and then open the document inside that suitcase. Do not use Font/DA mover 4.1 to do this. A bad font or sound will either cause a system crash or it won't open. Do not reinstall the corrupted font or sound in the System Folder. Use the original provided by the vendor.

LisaCalc 7/7: The NPV function is different

This article has been archived and is no longer updated by Apple.
The NPV function has changed in the 7/7 version of LisaCalc. In the old version (2.0), the first value of the cashflow was counted as the payment for the first period and was thus discounted (annuity due). The formula looked like this:

v1/(1+discount)^1 + v2/(1+discount)^2 + ...vn/(1+discount)^p

where v is the value of your cash flow, discount is the discount percentage, n is the number of the payment, and p is the number of the period.

In the new LisaCalc 7/7, the first value of the cashflow is not counted as the first period and not discounted (annuity arrears). The formula looks like this:

v1/(1+discount)^0 + v2/(1+discount)^1 + ... vn/(1+discount)^p

It's just another way of looking at the same function. Both are equally correct.

System 7: MS Mail "Send Note" Window Doesn‘t Close

My MS Mail "Send Note" window does not close when I click the close box. I have MS Mail, Suitcase II, and DAL extensions loaded.
This article has been archived and is no longer updated by Apple.
To correct this problem, change the loading order of the extensions, so that DAL loads after MS Mail and Suitcase II. Another alternative would be to remove the DAL extension from the System Folder, if it's not needed.

This may no longer be a problem with DAL 1.3 or greater, System 7 w/Tune-up, and/or MS Mail 3.0.
Published Date: Feb 18, 2012

System 7: Error Type -192 Appears when Removing Fonts

While trying to remove fonts from the System suitcase, a dialog box appears saying that the system is preparing to move them. It also shows the number of fonts. Then this error message appears: "The command could not be completed because a type -192 error occurred."

This article has been archived and is no longer updated by Apple.

This error message is being generated because you have a SAM (Symantec Anti Virus for the Macintosh) version earlier than 3.0 installed. This version of SAM recognizes that the System file is being altered, but doesn't know why. To resolve the situation, upgrade to a newer version of antivirus software.

Published Date: Feb 18, 2012

System 7: GemStart 030 Accelerator Control Panel Upgrade

I have a Macintosh Plus with a GemStart 030 Accelerator installed. When I open the Users & Groups control panel and then open a user icon, the window freezes. I cannot move, make changes to, or close the window, but I can access the menu bar.

Also, whenever I get a system error, I see only the upper portion of the dialog box. The lower portion isn't visible.
This article has been archived and is no longer updated by Apple.
The GemStart 030 Accelerator control panel version 1.3.3 is neither System 7 nor AppleTalk Phase 2 compatible and, therefore, may cause file-sharing and printing difficulties. To prevent this from occurring, try turning off the GemStart "Copy ROM into RAM" option.

There are two workarounds:

- MicroMac Technology, Inc. reports that GemStart version 2.03 or later is fully compatible with version 7.0 and AppleTalk Phase 2. Update the control panel with this version, which is a free upgrade.
- Until you get the update, remove the GemStart control panel from the Control Panels folder and restart the computer.

System 7: SideKick 2.0 Is Not Being Updated for System 7

SideKick 2.0 crashes with a bus error when I try to open a name in the address book.
This article has been archived and is no longer updated by Apple.
When running SideKick, turn off 32-bit addressing, and this feature will work.

Note that Borland International Technical Support said that SideKick 2.0 (which is not being updated) should not be used with any system software later than version 6.0.3. Otherwise, data could be lost or the computer may crash. The information can be exported to a text file and used with other programs.

For details, contact Borland Technical Support.

System 7: Compatibility Checker 1.0 Thinks Numeric HD Name Is ID

Compatibility Checker 1.0 does not run properly on a hard drive that has only numeric characters as the volume name.
This article has been archived and is no longer updated by Apple.
This is a known issue. This is a HyperCard limitation and cannot be fixed through Compatibility Checker itself. The program thinks that the numeric string, used as a hard-drive name, is a HyperCard button ID rather than a volume name.

The workaround is to rename the hard drive with a non-numeric name before running the Compatibility Checker.

System 7: Purpose of Notification Manager

Sometimes a diamond appears next to an application in the Application menu that is running in the background. What does the diamond signify?
This article has been archived and is no longer updated by Apple.
The diamond next to a running application in the Application menu indicates that the program has a message or an alert to display. The Notification Manager lets processes running in the background notify the user of messages or alerts without disrupting the process running in the foreground.

An example of an application that uses the Notification Manager is PrintMonitor. Rather than PrintMonitor taking control of the screen and becoming the active application, PrintMonitor alternates its icon with the Apple icon in the menu bar when it requires the user's attention. In addition, a small diamond is placed next to the application name in the Application menu.

The Notification Manager provides three alert levels:

- **Polite:** A blinking icon appears in the menu bar.
- **Audible:** The system beeps once.
- **Alert Box:** A dialog appears that the user must acknowledge.

Apple IIe Card: Software Version 2.0.x Features & Changes 5/94

This article describes the new features and benefits of the Apple IIe Card Version 2.0.x software.

This article has been archived and is no longer updated by Apple.
Version 2.0.x software has added many new features to the Apple IIe Card for the Macintosh LC. Here are the highlights:

The Macintosh LC IIe Card works in:
* Macintosh LC, LC II, LC III, LC 520
* Performa 400, 405, 410, 430, 450, 460, 466, 467, 550
* Macintosh Color Classic
* any future model that has an LC slot or LC-compatible slot.

To use the Apple IIe Card on a Macintosh LC II, Macintosh LC III, or Performa 400 series running System 7.1 or System 7.1P, you need version 2.2.1 of the Apple IIe Card software. You should upgrade to version 2.2.1 ONLY if you are using your Macintosh LC II with System 7.1. You can use the Apple IIe Card software version 2.2 with the original Macintosh LC, but it's not required.

System 7 Compatibility

Version 2.0 of the Apple IIe Card software is not compatible with System 7.0. Version 2.1 is compatible with both System 6.0.8 and System 7.0.1. The Macintosh LC II requires version 2.1 of the Apple IIe Card software. Apple recommends that users use 2.1 only if they need System 7 or Macintosh LC II compatibility.

Hard Disk Support

* Apple IIe files and programs can be stored on the Macintosh hard disk.
* Apple IIe ProDOS files and disks can be seen and manipulated on the Macintosh desktop.
* Apple IIe files and programs can be opened by double-clicking their icons.
* Apple IIe files can be moved, copied, renamed, and trashed in the usual Macintosh ways.

File Server Support

If a Macintosh LC has an Apple IIe Card installed, you can connect to file servers that contain Apple IIe files and programs.
* When connected to a file server over a network, you can use AppleShare Workstation software to connect to the file server.
* Starting up from a file server (sometimes called "network booting") is much faster than it was using the original Apple IIe.

MultiFinder Support

You can run the Apple IIe Card simultaneously with Macintosh programs, switching between them without quitting either.

Option Panel Changes

The Option Panel works in the same way. However, many improvements have been incorporated:
* When the Option Panel is open, the menu bar can be used to access desk accessories and, if running MultiFinder, to switch to other programs.
* The Option Panel is in a movable window.
* A new combination keystroke can be assigned to open the Option Panel (in addition to using Control-X-Esc).
* The Auxiliary Slot Memory Card option in the General Controls panel has been removed. To expand the amount of memory, use the Memory Expansion Card.

* There are two new ways to limit access to the Apple IIe Prefs file:
- The Get Info command in the Macintosh Finder can be used to lock the file to prevent any changes.
- The file can be hidden by dragging it to the System Folder to prevent anyone from accidentally trashing it.
* The General Controls panel has been rearranged.
* The Mouse panel has two additional options to make the mouse even more sensitive to your movements.

Card and Slot Changes
---
* An AppleShare Card has been added.
* A Printer Card has been added. Use this card to connect the printer to your computer either directly or over a network.
* The Network Printer Card has been removed.
* The Printer Port and the Modem Port cards both have been renamed Serial Cards. (Note that these two Serial Cards should not be used for printers; use the Printer Card instead.)
* The Serial Cards have special settings for both Apple modems.

Enhanced Printer Support

You can print to most Macintosh-compatible printers--whether the printer is connected directly or on a network. Also, you can set up and select Apple IIe printers using simple Macintosh methods.

Printing Changes

Once the cards, slots, and printing software have been set up, Apple IIe files are printed in much the same way as with the original software. However, the setup method has changed significantly. In the earlier version of the Apple IIe Card software, the Network Printing Card or a Super Serial Card was used. In version 2.0, the Printer Card and a Macintosh desk accessory called Chooser are used. Specific printing changes include:
* The Network Printing Card has been removed from the Option Panel.
* The Printer Card should be used for all printers, whether the printer is connected to your computer directly or over a network. The Super Serial Cards should not be used for printers.
* Regardless of the printer, when using the Printer Card, the Apple IIe program should treat the printer as if it is an ImageWriter II.
* The new printing system supports all Apple printers.
* The Macintosh Chooser desk accessory is used to select the printer.

Saving and Printing Apple IIe Screens
---
* Several menu commands can be used in the Option Panel to save, copy, print, and display Apple IIe screens.

System 7: Installing AppleShare without Installing File Sharing

Article Change History

09/14/92 - REVIEWED
* For technical accuracy.

Can I install AppleShare software on my Macintosh without installing the File Sharing software at the same time?

This article has been archived and is no longer updated by Apple.
To install AppleShare software without installing the File Sharing software, use the Installer's "Customize" option and select either "System Software for Any Macintosh" or "System Software for [your particular Macintosh model]."

Using the Installer's "Easy" option installs both AppleShare and File Sharing software.

Lisa Pascal: Problem Reading Directly Into Real Arrays

This article has been archived and is no longer updated by Apple.
In versions 1.2 and 2.0 of the Lisa Workshop, there was a problem with reading directly into a real array:

READLN(FILE,STUFF[2])

where FILE is a file and STUFF is a real array. The problem is fixed in version 3.0.
Published Date: Feb 18, 2012

System 7: Installing on Macintosh Portable RAM Disk

Can I use the RAM Disk on my Macintosh Portable to install System 7?
This article has been archived and is no longer updated by Apple.
Yes. The Macintosh Portable lets you create and use a RAM disk. You can install System 7 on a RAM Disk for faster performance and less hard disk access, which can extend the life of the battery.

To create a RAM disk on the Macintosh Portable:

1. Select the Portable control panel from the Control Panels folder.
2. Click the box next to "RAM Disk Size" and select the size. If the size you want is not listed, select "other" from the menu and choose the desired size. Note that a minimal System 7 install for a Macintosh Portable is about 971K. A dialog box appears telling you that the new RAM disk will be created when the system is restarted.
3. After closing the control panel, select Restart from the Special menu.

To make the RAM disk the Startup disk with a System Folder:

1. Run the Installer program as you would with any other volume.
2. When the installation process is finished, open the Control Panels folder and choose the Startup Device control panel.
3. Click the RAM disk to use as your startup volume.
4. After closing the control panel, select Restart from the Special menu.

Concerned about losing the information on a RAM disk? There are only two ways to erase a RAM disk on the Macintosh Portable:

- Remove all files from the RAM disk and select "none" from the "RAM Disk Size" pop-up menu in the Portable control panel.
- Remove both batteries from the Macintosh Portable.

Macintosh: How to Slow It Down

I am trying to use a Macintosh SE/30 running SoftPC, so I can download from a DOS device directly into the SE/30 through a port. My problem is that the SE/30 is going so fast that it is not reading the information I am trying to dump. Is there some way I can slow it down?

This article has been archived and is no longer updated by Apple.

If you're using System 6, try launching MultiFinder and running one or more applications in the background. This should slow down processing somewhat. In System 7, just launch some applications. Turning on file sharing will also slow down processing.

Published Date: Feb 18, 2012

AppleShare File Server: Forcing Applications to Run Concurrently

I tried to install a program on my AppleShare server to run concurrently. I followed the instructions (which basically were to copy it to the server folder and then restart) but cannot get it to show up on the file menu. The program is Netway 3287, which routes CMS printing to the LaserWriter Any hints?

This article has been archived and is no longer updated by Apple.
It's possible to force an application to run concurrently with the AppleShare File Server, but if the application isn't already set up that way, you may run into problems. Contact CMS for the details. For contact information, search the Tech Info Library under "CMS".

AppleTalk: Internet Router Phase I vs Phase II Fix

We are running an AppleTalk Phase I network with six zones connected through a Banyan Vines server to an Ethernet network with a single zone. One AppleTalk zone is connected through a Hayes Interbridge to another AppleTalk network in another location. The issue is that the AppleTalk Internet router won't cross the Hayes Internet bridge to the AppleTalk network at the remote site. My goal is to run Microsoft QuickMail with Banyan's Quick Mail through the Hayes Internet bridge to my remote site. If the Internet Router is not compatible with the Hayes internet bridge, then I must find something else.

This article has been archived and is no longer updated by Apple.

You probably have an AppleTalk Phase I versus Phase II issue. Most Hayes Interbridges are Phase I devices, while an unaltered Internet Router is Phase II. An "upgrade utility"--an INIT--comes with the Internet Router. Once installed in the System Folder of the router CPU, the INIT lets the Router pass Phase I packets. As a short-term workaround, you can install this to get up and running.

Due to the complexity of the network, we advise upgrading all devices to AppleTalk Phase II. With the zones and routers you mentioned, the Phase II protocols will be more efficient. Usually, this upgrade can be done through software. The Interbridge is the exception: it requires a ROM upgrade.

ProDOS: Conflict between Versions Backup II

I backed up my hard disk with Backup II version 1.01, and the drive went down (total loss of data). While trying to restore from the backup I get through 13 of 34 disks, and then I get a DATE/TIME STAMP DO NOT MATCH error. I have looked for the date and time stamp bytes on the disks to no avail.

Can I fix Backup II to not look for a DATE/TIME STAMP? Which bytes should I look for on the bad disks? I have looked at the information on the disks in question and the data is there.

This article has been archived and is no longer updated by Apple.
The actual problem may be with your versions of ProDOS and Backup II. Specifically, versions of Backup II before 1.1.1 are not compatible with any ProDOS version greater than 1.1.1. If your Backup II and ProDOS are incompatible, you have two options:

* Use Backup II v1.1.1, which will read your backup disks
* Downgrade ProDOS to 1.1.1.

The Date/Time stamps for a ProDOS volume reside in bytes $1C-$1F of block 2. Matching these against previous volumes may solve the problem.

To help you find block 2, here is a good formula for converting ProDOS blocks to DOS 3.3 sectors:

Block = (8 * Track) + SectorOffset	
Sector:	0 1 2 3 4 5 6 7 8 9 A B C D E F
SectorOffset:	0 7 6 6 5 5 4 4 3 3 2 2 1 1 0 7
Half of Block	1 1 2 1 2 1 2 1 2 1 2 1 2 1 2 2

It looks like the bytes you need are on Track 0, Sector 11 (first half of block).

TA46607_Macintosh_Classic_Classic_II_Screen_Brightness_Adjustment_(TIL08099).pdf

Macintosh Classic, Classic II: Screen Brightness Adjustment

I saw that the Macintosh Classic and Classic II's screen brightness is adjusted via System software. If I use System 6.0.3 in my Classic or Classic II, how can I control the screen brightness?

This article has been archived and is no longer updated by Apple.
The Macintosh Classic is incompatible with any System Software version earlier than 6.0.7. Even if there were a way to use the Brightness CDEV with System 6.0.3, the Classic would not start up. The Macintosh Classic II needs to use System 7.01 in order to function correctly.

Published Date: Feb 18, 2012

TA46608_LisaWrite_Landscape_Printing_(TIL00810).pdf

LisaWrite 2.0: Landscape Printing

This article has been archived and is no longer updated by Apple.
There is a problem printing in Landscape mode in LisaWrite 2.0. Missing and partly formed characters are printed in the upper right portion of a write document printed 'while you wait'. (Versions 3.0 and 3.1 of Lisa 7/7 don't give you the option of printing 'while you wait', so the problem doesn't occur with these versions.)

The workaround is to print 'while you work'.

Macintosh Classic: Internal Drive Questions

1) What is the drive seek time of the Macintosh Classic?

2) What is the initial interleaving?

3) Can dealers install third-party drives without voiding the computer's warranty?

4) Who makes the drives, and does Apple have multiple sources?

This article has been archived and is no longer updated by Apple.

1) Question: What is the drive seek time of the Macintosh Classic?

Answer: The seek time for all Apple 1/3-height drives is 25 milliseconds.

2) Question: What is the initial interleaving?

Answer: The interleaving is based on how fast the circuits can keep up with the data flow. The Classic has an interleave ratio 1:1.

3) Question: Can dealers install third-party drives without voiding the computer's warranty?

Answer: As long as you make no modifications to the Classic (the dealer must use Apple's mounting scheme, not drill new holes, and the like) then yes.

4) Question: Who makes the drives, and does Apple have multiple sources?

Answer: Apple cannot comment on drive vendors; vendors may change from model to model. The guarantee is, however, that any hard drive will have an average access time of 25 milliseconds.

Article Change History:
29 Nov 1995 - Updated format.
16 Oct 1992 - Corrected the interleave ratio.

Macintosh: Error 51 "Unserviceable Slot Interrupt"

What is error ID=51? I get a system bomb when I try to log on to my Ethernet network.
This article has been archived and is no longer updated by Apple.
That error is: "Unserviceable slot interrupt."

In general, this type of error is caused by a corrupt operating system, Ethernet driver, or a software incompatibility between any of these and INITs or CDEVs.

Try removing and re-installing the operating system and Ethernet drivers. If that fails to solve the problem, try removing all unnecessary third-party INITs and CDEVs. If the system works at this point, re-install them one at a time and restart each time to find the culprit.
Published Date: Feb 18, 2012

Apple IIGS: $8002 Error

I've been getting the "$8002 error" when I drag anything over to my second partition under GS/OS 5.0.2. After pulling out other cards, I'm left with my high-speed SCSI card and my Applied Engineering memory expansion board. This is on an older GS "01" board.

This article has been archived and is no longer updated by Apple.
There are two possibilities.

The first, less likely, possibility is that there is a soft error somewhere on your hard drive, and it's preventing GS/OS (actually, the SCSI driver) from the reading some necessary information from the second partition. If re-installing GS/OS and the High-Speed SCSI drivers doesn't solve the problem, you probably will have to reformat the hard drive.

The second is slightly more likely: Some Applied Engineering cards use the DMA channel to move information. The IIGS has only one DMA channel, and the High-Speed SCSI card may be fighting the AE card for access to the channel.

Here are two things to try: Either turn off the DMA access on the High-Speed SCSI (DIP switch 1) or remove the AE card completely from the system and then test. I believe that Applied Engineering has an update for some of their memory cards to deal with this situation. If you find that this is the problem, try contacting them for a possible fix.

Macintosh Plus, SE, and Classic: Speed Comparisons

A Macintosh SE seems noticeably faster than a Macintosh Plus. Yet, their spec sheets show the same processor and MHz speeds.

Macintosh SE Spec Sheet
Processor: MC68000, 32-bit internal architecture, 7.8336 MHz clock frequency

Macintosh Plus Spec Sheet
Processor: MC68000
1. 32-bit architecture
2. 8 (7.8336) MHz frequency

Macintosh Classic Spec Sheet
- Microprocessor: 8 MHz MC68000 CPU
- Internal architecture: 32-bit

Is MHz a reliable measure of apparent speed? How does the Classic compare with each of them?

This article has been archived and is no longer updated by Apple.
The clock speed of the computer is not always the overriding factor in performance. For example, a hideously-complicated program can takes an hour to draw a picture, but a better-written program can do it in ten minutes. Here, it depends on how compact the code is, not the processor speed.

The clock speeds are identical, but the software burned into ROM is different, causing the three systems to run at slightly different speeds.

The Macintosh SE is possibly 15 percent faster than the Plus, and the SE/30 is four times faster. In any event, the Classic is faster than the Plus by a maximum of 25 percent. That assumes that you're doing only those functions that have been optimized in the Classic. Usually, you'll see a slight increase in performance, and in some you'll see no difference. It all depends on what you're doing.

There are hundreds of things that influence performance. At the bit level, all three machines process a single processor instruction in exactly the same time. Things like processor caching will decrease the time it takes for that instruction to be loaded from memory, so performance increases a little there. Taking from the example above, if a routine is more compact, then it will do its job in fewer instructions. This means the system does the function faster. All this goes into determining the phrase, "...up to 25 percent faster than the Macintosh Plus."

Macintosh 12-Inch RGB Display: Compatible Systems

I have a problem driving the Macintosh 12-Inch RGB Display with an 8-bit video card in a Macintosh IIcx.
This article has been archived and is no longer updated by Apple.
Not all Macintosh video sources support the Macintosh 12-Inch RGB Display. The following Apple video outputs support this monitor:

- Macintosh Display Card 4*8 and Macintosh Display Card 8*24
- Macintosh IIci built-in video
- Macintosh IIsi built-in video
- Macintosh LC built-in video
- Macintosh LC II built-in video

Notes:
All previous video cards do not work with the Macintosh 12-Inch RGB Display. At the time these cards were developed, the timing for the Macintosh 12-inch RGB Display was not known and, therefore, does not support the proper video signaling.

The Macintosh Display Card 8*24 GC does not work with the Macintosh 12-Inch RGB Display. The card is designed for high-end systems, and the Macintosh 12-Inch RGB Display is for inexpensive systems.

AppleShare Print Server: Correcting False Usernames

We are using AppleShare Print Server as a server for both IBM and Macintosh computers.
But, there are occasions when an IBM user prints, and the statistics for that print job don't appear. That is, the username comes up as "Untitled", and the number of pages isn't correct. What's going on? We are using Apple and DayStar Digital cards in the IBMs. Neither card seems to make a difference.

We tried turning the server off and printing a job from the PC and then one from the Macintosh. Here's what we got: We tried using both Microsoft Word and WordPerfect (on the PC) and WriteNow and MS Word (on the Macintosh). The dialog box we got alternated between "Waiting for LaserWriter", "preparing data", and "printing" until it actually started printing the Macintosh document. There was no mention of the user or document that we were waiting for. So, it appears that the drivers are not doing what they should be.

Another server problem is that there have been occasions when a person prints a paper (on a Macintosh) and the title and username are not correct, but seem to be substituted from a previous job. For example, user "James" prints document "Thesis", and the cover sheet is correct. Then user "Sue" prints document "Junk" and the cover sheet (and name on the server log) is "James". We have replaced the server software already, and this has fixed the problem for a few days, but then it re-appears.

This article has been archived and is no longer updated by Apple.
Both of these problems could be related to a single cause. Following the steps below may solve both problems:

1) "Uncapture" any captured printers.

2) Restart the server with a diskette (if this server is also an AppleShare File Server, use the Admin diskette).

3) Inside the ServerFolder, locate the captured printers' folders and trash them. Their names will be in the format:

Q_<printername>_*

where * could be a zone name.

4) Restart the server again from diskette, rebuilding the Desktop on the hard drive.

5) If this is an AppleShare File Server, run the Admin program from the floppy to re-prepare the hard drive and quit immediately.

6) Restart as usual, and recapture the printers.

This should solve any type of directory problems the server may be having, and force the Print Server to create new spool folders.

TA46617_Macintosh_SCSI_Interleave_Factor_(TIL08110).pdf

Macintosh: SCSI Interleave Factor

What is the SCSI interleave factor for the Macintosh Classic, LC, and IIsi?

This article has been archived and is no longer updated by Apple.
The interleave factor for the Classic, LC and IIsi are all 1:1 because of improved SCSI circuitry.

TA46618_Macintosh_TwoPage_Display_and_Builtin_Video_(TIL08111).pdf

Macintosh: Two-Page Display and Built-in Video

Why doesn't the built-in video of the Macintosh IIci, IIsi, and Macintosh LC support the Apple Two-Page Display? Couldn't you just allocate more RAM to video?

This article has been archived and is no longer updated by Apple.
With the Two-Page Display and built-in video, the issue was not the amount of RAM needed to drive the display, but the amount of "cycle stealing" that would occur. The degree of performance degradation for the microprocessor was unacceptable, so Apple removed the option entirely.

Macintosh XL: Unwanted Shutdown

My Macintosh XL intermittently dims its screen and shuts off. While the screen dims, the HD still runs. The dim effect is not a normal tube shut-down. Rather, it is the XL dimming the screen just as it does when you normally choose Shut Down from the Finder's Special menu.

The problem is not application-specific and does not seem to follow any type of schedule. It seems random.

This article has been archived and is no longer updated by Apple.
As the intermittent shutdown procedure is the same as a forced-shutdown (via the menu), and that procedure is stored in software rather than firmware, you are looking at a software or software-related cause. On the hardware side, you could have damaged RAM or motherboard, but it's not very likely. You would see many more problems than this if you had a failing component.

We suspect either MacWorks Plus, system software, or (possibly) an INIT or CDEV. Something is either corrupted or conflicting with another piece of software.

Try reloading MacWorks Plus and reinstalling the operating system.

Lisa Workshop: Transfer Program

This article has been archived and is no longer updated by Apple.

In Transfer, there is a Break key for a hard break: it disconnects you. The easiest way to get around it is to send an XOFF from the keyboard or imbedded in your file (you would have to write a program to put it there). The file is then sent without filtering.

Personal LaserWriter LS: Missing Excel Page Setup Options

When printing from Excel 2.2 or 3.0, some of the Page Setup options are dimmed and not accessible. Do I have a problem with my Personal LaserWriter LS driver?

This article has been archived and is no longer updated by Apple.

No. Microsoft Technical Support has verified that certain options under Page Setup are not accessible when printing from Excel 2.2 or 3.0 to the Personal LaserWriter LS. The inaccessible options include 75% and 50% under the Size option and the Precision Bitmap Alignment option under Printer Effects. There is no workaround at present.

Microsoft Word and Microsoft Works take full advantage of all of the Personal LaserWriter LS options.

Macintosh: Advantages of System 6.0.5 for Some Products

Not all Macintosh users will upgrade to System Software 7.0, choosing instead to use System Software 6.0.x. For those users, this article describes the advantages of using System Software version 6.0.5 with some Apple products, including some that are compatible with System Software 7.0.

This article has been archived and is no longer updated by Apple.
The Macintosh IIfx and some display cards require system software version 6.0.5 or later. Additionally, system software 6.0.5 may be appropriate for other Macintosh systems in the installed base. System software 6.0.5 transparently coexists in networked environments with Macintosh system software versions 6.0.2, 6.0.3, and 6.0.4.

The following products require system software 6.0.5 or later:
* Macintosh IIfx
* Macintosh Display Card 8*24 and Macintosh Display Card 8*24 GC
* Third-party software or hardware products that say "Requires 6.0.5 or later" on the box.

Apple recommends 6.0.5 (or later) for the following products:
* Macintosh Portable
* Macintosh IIci
* 32-Bit QuickDraw

Here is a brief description of the changes made in system software 6.0.5 to better support these Apple products.

* Macintosh Portable
System 6.0.5 fixes two problems associated with the Macintosh Portable.
1) A communications problem occurs when the Macintosh Portable is connected to serial devices.
Symptom - The Macintosh Portable loses track of printers and modems after coming out of Sleep mode.
2) A power-consumption problem is encountered when the Macintosh Portable is shut down while connected to AppleTalk.
Symptom - The battery discharges quickly when shut down under these conditions.

* Macintosh IIci
System 6.0.5 addresses two compatibility problems.
1) Control-break characters received through the serial port cause a system crash.
2) 32-Bit QuickDraw version 1.2 is unable to use zero-width characters. Music programs and accented characters use zero-width characters extensively.

* 32-Bit QuickDraw
System 6.0.5 increases performance and offers additional dithering capabilities as well as support for variable-resolution PICT images. (Font information is stored in PICT images.)

MacWorks: Starting Up From a Hard Disk

This article has been archived and is no longer updated by Apple.
There are several versions of MacWorks, each with a different start-up procedure. The two later versions let you access the built-in 10-megabyte hard disk (in a Macintosh XL) or a 5- or 10-megabyte ProFile connected to the built-in parallel port of a Lisa 2.

MacWorks: 682-0103-A

After the Macintosh XL starts up from this original version of MacWorks, the system can run almost any Macintosh application residing on diskette. But this version cannot access a hard disk.

MacWorks: 682-0103-B

MacWorks Revision B can access Macintosh software and files on diskette, as well as on a hard disk installed with the MacWorks Hard Disk Install program. Once you install MacWorks, you can access the hard disk by starting up from MacWorks XL and then inserting the System Diskette.

MacWorks XL: 682-0103-C and MacWorks: 682-0103-C

MacWorks Revision C is not an official release and could damage documents and data stored on the hard disk. If you use this or earlier versions of MacWorks, be sure to upgrade to MacWorks XL Revision D, available from Sun Remarketing, P. O. Box 4059, Logan, Utah 84321.

MacWorks XL: 682-0103-D

MacWorks XL lets you to start up from the hard disk. It also lets you use additional Macintosh software, such as Jazz and XL/Serve by Infosphere. This version supports AppleTalk and the LaserWriter. This version is identified by the product number on the diskettes and by the display "MACWORKS XL 3.0 COPYRIGHT 1985 - APPLE COMPUTER" that appears on the screen during startup.

MacWorks XL enables you to start up off the hard disk directly if:

1. You've previously used the accompanying hard disk install program to install MacWorks on the hard disk, and

2. The hard disk is being used exclusively for Macintosh software.

If the hard disk contains both Lisa and Macintosh software, you must first start up from MacWorks XL, but even this procedure is faster than with previous versions. Hold down the option key and start up the Macintosh XL if you want to start up with software from the microdisk drive.

The Hard Disk Install program that comes with MacWorks Versions B and D lets you initialize the hard disk to either 1) run exclusively Macintosh software, or 2) to run both Macintosh and Lisa software. To share the hard disk with Lisa software, you must first partition the hard disk with Lisa Office System software (selecting Share during the Lisa software install procedure); you must then use the Hard Disk Install program to initialize the Macintosh portion of the hard disk.

If you use BOTH 1) the built-in parallel port connected to a hard disk, or the built-in hard disk after it's been formatted exclusively for Macintosh software, AND 2) a Parallel Interface Card connected to a hard disk formatted for Lisa software, then you'll have to select the hard disk you want the system to start up from. The system will automatically start up from the hard disk last used, provided you haven't unplugged the system or

changed the Preference settings. To start up from the other hard disk:

1. Press the On-Off button.
2. Wait for the memory board test.
3. Hold down the Apple key while pressing a number key as listed below:

To start up from:	press these keys:
Internal hard disk:	Apple 1
Built-in parallel port:	Apple 3
Interface card:	
slot one, lower port	Apple 4
slot one, upper port	Apple 5
slot two, lower port	Apple 6
slot two, upper port	Apple 7
slot three, lower port	Apple 8
slot three, upper port	Apple 9

Macintosh: Mac Handwriter for Kanji Input

This article describes the Macintosh input device marketed by Communication Intelligence Corporation.
This article has been archived and is no longer updated by Apple.
Communication Intelligence Corporation offers a product that lets Macintosh computers read handwritten Chinese and Japanese characters. Currently this product is not distributed in the U.S.

The Mac Handwriter lets computer users give commands or data to Apple's Macintosh computers by writing characters on a small pad. This eliminates the need for a keyboard.

This article provides information about a non-Apple product. Apple Computer, Inc. is not responsible for its content. Please contact the vendor for additional information.

Macintosh: DiskTwin for Disk Duplexing

This article is about DiskTwin, a product sold by Golden Triangle Computers, Inc.

This article has been archived and is no longer updated by Apple.
DiskTwin is a Macintosh software package that works with a NuBus card and a second SCSI bus, to make a copy of the contents of a primary hard drive onto a secondary hard drive. Technically, this operation is known as disk duplexing.

Disk duplexing is a technology widely used in the mainframe and minicomputer world and in large microcomputer networks to ensure continuous operation where users cannot afford to lose any data or experience down time.

Here are the steps required to use DiskTwin:

1) Drop the DiskTwin control panel device (CDEV) into your System Folder.

2) Place the DiskTwin NuBus card in your Macintosh.

3) Attach a drive of the same kind as your primary disk onto the DiskTwin card. For example, if you have an Apple Quantum 80 internal, connect an Apple Quantum 80 external to the DiskTwin card.

4) Restart your computer, and select the drive you want to copy. The twin is invisible to the Macintosh desktop so it can't be used accidentally.

When you do need it, you can immediately mount the twin onto the desktop from the DiskTwin control panel.

DiskTwin runs continuously, creating a copy of your primary disk as often as you save to disk. DiskTwin won't slow your system. When your hard disk fails, mount the twin and you're back in business. Should the Macintosh SCSI hardware fail, your DiskTwin SCSI port remains operational.

You can find the address and phone number for Golden Triangle Computers, Inc. in a separate article in the Tech Info Library.

System 7: Third-Party Drives and Virtual Memory

We update the hard disk drivers for Apple drives if the user is to make use of virtual memory. Do users of third-party hard disks need to update their drivers?

This article has been archived and is no longer updated by Apple.

Not necessarily. The update corrects something in Apple's SCSI drive. Third-party drives don't need the update unless their manufacturer says they do.

Published Date: Feb 18, 2012

System 7: Disk Drive Activity Light

When running System 7 without virtual memory and during periods of no user activity, the disk drive becomes active for a few seconds. What causes the disk drive light to flash?

This article has been archived and is no longer updated by Apple.

The light flashes because the Finder is busy updating. If you'd like this not to happen, turn the file system cache up, and the Finder won't need to update as often.

The disk drive light will also flash when File Sharing is turned on and other people are accessing the disk.

Published Date: Feb 18, 2012

System 7: No Need for HeapFixer and HeapTool Utilities

How has memory management changed in System 7 relative to system heap and INITs? Specifically, will utilities like HeapFixer and HeapTool still be necessary for people who are running a lot of INITs?

This article has been archived and is no longer updated by Apple.

HeapFixer and HeapTool don't do anything in System 7. The system has changed such that these utilities won't be needed. The function HeapFixer and HeapTool perform is done by the new boot code in System 7. The system heap will now dynamically grow as extensions allocate more space.

HeapFixer had value with system software version 6.0.X because INITS would add to the system heap, and the heap filled up. Looking at the system bar in the About box and adjusting the size so that enough space is left over won't work any more.

The system software indicator in System 7 includes a lot more than just the system heap, so it can't be used as an indicator of how much space is currently available. And since the system heap is dynamic in System 7, even during startup, any adjustments made by the HeapFixer and HeapTool utilities will just be overridden by the system.

Published Date: Feb 18, 2012

System 7: Use of Virtual and Physical Memory

When using System 7, why can systems that are not 32-bit compatible access 13 megabytes of virtual memory, but only 8 MB of physical memory?

This article has been archived and is no longer updated by Apple.

The memory map in a 24-bit system only allows for 8 MB of RAM, 6 MB NuBus, and 2 MB ROM and I/O. Virtual memory will use the allocated memory of a NuBus card that is not in use. If you were to put more physical RAM in a Macintosh II running in 24-bit mode, the system would use only 8 MB, and the rest would be ignored.

System 7: Rarely Need to Initialize HD Before Installing

Do I need to reinitialize my hard disk before installing System 7?
This article has been archived and is no longer updated by Apple.
In most cases, there is no need to reinitialize any hard disk on which you plan to run System 7.0, unless the disk has been damaged in some way.

If you are using a third party hard drive, you should contact the manufacturer to get the suitable driver to update the SCSI driver before installing System 7.

Also, if your Apple drive was updated with an older version of Apple HD SC Setup, your partition size will be smaller, so if you then, update your drivers again with a more recent version of HD SC Setup, you will be told you do not have enough room. If you run into this situation, you will need to reinitialize your hard drive and then install System 7.

If you are planning to run Virtual Memory, use HD SC Setup version 7.0 to update the SCSI driver. This requires that you start up from the Disk Tools floppy disk, choose the target drive, and click on Update. This process takes a second or two to complete, and does not require any reformatting, or reinitializing, of your hard drive.

Note: Be sure to back up your hard drive before you initialize your drive. It is also a good idea to back up before you update to System 7.

System 7: Group Upgrade and Compatibility on Novell NetWare

Why does the System 7 group upgrade fail when using Novell NetWare server version 3.11?
This article has been archived and is no longer updated by Apple.
Version 1.1 of the Migration Guide corrects the Novell NetWare upgrade station issue. With version 1.0 of the Migration Guide, you can't use Novell NetWare servers (both version 2.15 and 386, now called version 3.11) as upgrade stations when performing System 7 group upgrades.

The behavior occurs only when the creation time of the System 7 files ends in an odd-numbered second. This is due to the way MS-DOS and the Novell server keep time. They understand only even-numbered seconds. In the released version of System 7, all files have creation times with even-numbered seconds.

Versions of Novell NetWare for the Mac that are compatible with System 7 are:

- Novell NetWare 286 Server, NetWare for the Mac version 2.0 is partially compatible. Version 2.2 is fully compatible.
- Novell NetWare 386 Server, NetWare for the Mac version 3.0.1 or 3.0.1.1.

TA46633_Lisa_SHIFTOPTION_(TIL00814).pdf

Lisa 7/7: SHIFT-OPTION-7

This article has been archived and is no longer updated by Apple.
The Lisa Office System Manual for 7/7 documents a procedure to get screen dumps to disk. When this SHIFT-OPTION-7 keystroke procedure is performed, the diskette drive makes the noise of a diskette access. Yet, after this access, there doesn't seem to be anything other than missing blocks on the diskette. And even though the workshop can recognize the file that the disk access created, this file is of little use without some software that is unavailable to the casual user. The tried and true SHIFT-OPTION-4 screen dump is still the best procedure for most users.

SCSI Termination and External Hard Drives

I am having some problems with my Apple 160MB hard drive. I have a Macintosh IIci, two monitors, an internal HD, and a SCSI cable (which is about four feet long with one SCSI extender) with a SCSI terminator attached.

When the system is set up without the external 160MB drive, it works fine. But when I attach the drive, the Macintosh IIci won't start up. I've replaced terminators and swapped some SCSI cables. However, if I put an Apple 40MB hard drive in place of the 160MB drive, it works.

This article has been archived and is no longer updated by Apple.
SCSI termination problems are difficult to diagnose. Besides the suggestions below, there are a number of other articles that may be of help by searching under "SCSI" and "termination".

1) Make sure the external drive is turned on before the Macintosh is.

2) Make sure the SCSI ID on the external drive is not set to zero. It should be between 1 and 6.

3) Try the 160MB drive on another machine, preferably without an internal hard disk. If it has problems it could be the cable or the hard disk.

4) Swap the cable and the terminator if neccesary.

AppleTalk Printing: Apple IIe Workstation Card Slot

I want to connect a Macintosh II and an Apple IIe to an ImageWriter II over AppleTalk.

A Workstation card was installed in the Apple IIe, the necessary LocalTalk cables were used, SW-4 was switched for AppleTalk, and AppleTalk was selected in the Chooser. This did not work.

I then installed AppleShare into the Macintosh II. The Macintosh now prints, but the Apple IIe does not. Instead, it gives the message "No boot server -- trying other slots".

What am I doing wrong?

This article has been archived and is no longer updated by Apple.
The Workstation card must be installed in a higher-numbered slot than the disk interface card, otherwise the Apple IIe will try to start up over the network.

* If you WANT the Apple IIe to start up over the network, you must also install the Apple II Setup on the Macintosh II file server. This is a separate disk (AppleShare File Server Apple II Setup Disk). You would also need to copy Chooser.II to the server.

* If you DON'T want the Apple IIe to start up from the server, but rather to print to the ImageWriter II, then move the workstation card to a lower-numbered slot than the disk interface card and boot your workstation disk and run Chooser.II.

One other problem might be that you are running Chooser.II, getting a connection, and then inserting your application disk and restarting. This doesn't work. You have to run Chooser.II from the application disk or launch the application by pathname after running Chooser.II from the workstation disk.

EtherTalk: Troubleshooting Slow Performance

I have an EtherTalk card that seems to be running very slow on my Macintosh. My EtherTalk software is version 2.01. Can you help?
This article has been archived and is no longer updated by Apple.
The version that you are using should be fine, although there are newer versions available that may improve your computer's EtherTalk performance.

Make sure the network is properly terminated. Also, try running a network performance utility program to track the network's performance. This will show if an unusual number of packets are getting damaged or lost.

Check software, network (termination, topology, and so forth), and the card as well.
Published Date: Feb 18, 2012

AppleShare Print Server: "Stack underflow" Is PostScript Error

Are there any conflicts between AppleShare Print Server v2.01 and Microsoft Excel for Macintosh v2.2?

I am having difficulty printing Excel spreadsheets to a captured LaserWriter. I get no error messages at the workstation, but I get an error page with a message about a 'Stack underflow' error and the job doesn't print. If I print the document several times (half dozen or so) the job finally prints.

This article has been archived and is no longer updated by Apple.
"Stack underflow" is a PostScript error. Adobe's description of the error is: "An attempt has been made to remove an object from the operand stack when it is empty. This usually occurs because some operator did not have all of its required operands on the stack."

There is no way a user can cause this error. The more likely problem is a software incompatibility. Excel 2.2 and AppleShare Print Server 2.01 have no known problems. To see if the problem is actually related to the Print Server, try a bypass print. If the same document works consistently when printing directly, assume there is a conflict with Print Server and something else.

The problem could be related to the System file on the server. Reinstall System 6.0.5 on the server then use the Network Products Installer disk to reinstall AppleShare and Print Server. This process ensures that no resources in the System file get downgraded in the installation process.

Apple‘s Bar Code Format

I am trying to read the bar codes on the boxes of Apple products. What format does Apple use, and what software must be used to reliably read the bar codes?

This article has been archived and is no longer updated by Apple.

The bar code standard that Apple uses is code 39, a very common code. Apple's bar code software is proprietary, developed for internal use only, and will not be released to anyone.

Published Date: Feb 18, 2012

AppleShare: IBM Software Can‘t be Fully Copy-Protected

Is it true that IBM software on AppleShare server cannot be fully copy protected?

I am running an AppleShare file server (v2.01) containing a number of IBM software items. These application files have been marked as "copy protected" using the AppleShare administrator. Logging in from a Macintosh and examining the files with MacTools shows them to have the "protected" bit set. They cannot be dragged to a local Macintosh hard disk; if I try, I get the message "Cannot be duplicated or copied".

However, these items can be copied by IBM users, using normal command-line copy commands! As far as I can determine, there is no way to prevent piracy of any IBM software placed on the AppleShare server.

This article has been archived and is no longer updated by Apple.
AppleShare's copy protection feature was put in as an aid for Macintosh users, and it built on an old feature of the Macintosh file system. MS-DOS is not even aware of our copy protection bits, so there is no way to get a COPY command to respect this level of protection without being extremely intrusive into the operating system (and causing a good chance of incompatibilities with future operating system releases).

We don't know of a way to keep DOS users from copying applications from the server while still having access to run the program.

One solution is to distribute applications to the individual users who need them and use the file server only for data.

Apple Serial Numbers are Mostly Random Digits

I'm trying to track down the Macintosh model that these model and serial numbers apply to:

M5525 Macintosh IIfx? sn F3026MEAC40
M5780 Macintosh IIci? sn F1031DBY740

This article has been archived and is no longer updated by Apple.

It is sometimes impossible to tell what the factory configuration was by the model number printed (or stamped) onto the unit. The model number designates a "family" of computers and has only one absolute requirement: the first letter (M = Macintosh, A = Apple II, etc.). The other digits are essentially random.

That last 5-6 digits in the serial number usually end with the model numer, for example, F1234HYD34M5000. The M5000 is the model number.

In some specific cases you can figure it out, though: there was only one Macintosh 128K, for instance. In your case, however, we can't determine what the initial configuration was (which would enable us to discover the Finished Goods part numbers, eventually).

Shiva NetSerial: Capable of NetComm "Hunt Group"

I have an AppleTalk network (40 workstations, two servers, bridge, and so forth). I need to add 10 shareable serial ports to bridge into an existing Wang system.

Ideally, I would like to find some device like a comm-port server; something with up to ten ports that would manage the allocation of the ports. I have considered using ten Shiva NetSerials, but I do not like the "trial and error" method of finding an available NetSerial.

Does anyone make a device like this? Apparently there is something like this in the Novell world, where a PC is dedicated to be a comm server, and manages all shared-port access. Any ideas?
This article has been archived and is no longer updated by Apple.
From your description, it sounds as if you desire a network communication "hunt group"-type service; if the first communication server is busy, it will hunt automatically for the next available communication server.

You can do this right now with the Shiva NetSerials. Simply use the Chooser to choose all of NetSerials you wish to have in your "hunt group" and your call will be routed through whichever NetSerial is available. Because the NetSerial is an independent (after initial configuration) network device, you will not need to dedicate a computer to manage it.

Apple II and II+: Problems with keypresses on the keypad

This article has been archived and is no longer updated by Apple.

A keypress on the numeric keypad is only retained as long as the key is held down. Whenthe key is let up, the keyboard returns to its previous state (with the keythat was last pressed on the keyboard at location $C000). This causes manystrange problems, like having to hit the key longer to have it recognized.

There is no way to correct this on the current keypad because of the limitations of the keyboard encoder chip.

Apple IIGS: Troubleshooting "Out of RAM 04" Message

How much memory does an Apple IIGS need to run System v5.0.2?

I was told 768K, but when I tried to boot a system disk on an Apple IIGS with an expansion board installed, and with the entire first bank populated (top line of card full, top jumper not connected, bottom one connected), I got an "out of RAM" 04 message on the Apple IIGS.

I want to run GS/OS 5.0.2 over the net from a server, but if it can't even boot standalone, what do I need to run the net? Is 768K enough? Isn't that what I have? (256 + 512 (logic + add on))

This article has been archived and is no longer updated by Apple.
GS/OS should boot on a standalone Apple IIGS with 512K of RAM. If network services are going to be used, 768K is required.

Check to see if you have a RAM disk created in the Control Panel. Perhaps the RAM on the logic board or the memory expansion card is faulty; try running diagnostics. The card could be misidentifying the amount of RAM (because the jumpers aren't read correctly by the card even though they are set correctly).

LaserWriter IINTX: Q & A on Storing Fonts on Hard Drive

I'm using a 20MB SCSI hard drive with my LaserWriter IINTX. There didn't seem to be any problems, and the Laser Installer software recognized the hard drive as being online to the LaserWriter IINTX.

Then I installed all my Laser fonts to the hard disk, but when I ran the Laser Installer software, it did not recognize any of the fonts installed to the hard disk. It did not even recognize that a hard disk was connected (although the Laser did start up with the hard drive attached, and the drive-active light was on).

The software only gave a readout of the internal laser fonts -- not those installed on the hard disk.

1) How do I ensure that the hard drive is correctly connected and available as a font resource?

2) Can I install screen fonts on the hard drive, or only printer fonts?

3) Do I remove all printer (and screen) fonts from the System Folder on my Macintosh after they are installed to the LaserWriter IINTX hard disk?

4) My hard drive crashed, and my System Folder was corrupted while I was installing screen fonts to the system file using Font/DA Mover. What might have caused this? Is there a limit to the number of screen fonts that I can have installed to the system file? Is there a limit to the number of items that I can have in any folder?

5) Where do I get more complete information on the installation and support of this environment?

This article has been archived and is no longer updated by Apple.
It sounds like the problem was either with what fonts were installed or the process you used to install them.

1) When you run the LaserWriter Font Utility, if the drive is recognized and does format, then the drive is connected properly and operational.

2) No, you can't install screen fonts.

3) You will need the screen fonts on the workstation. Downloadable fonts on the workstation are unnecessary, but do not harm anything.

4) There is no theoretical limit to the number of screen fonts you could install in your System file, but you would eventually run out of RAM or disk space. The limit of files per folder is 64,000.

5) The LaserWriter IINTX manual shows how to make the connections properly and format the disk. If these processes work, the drive is operational.

Published Date: Feb 18, 2012

LaserWriter IINT: Memory Allocation

I have a LaserWriter IINT with 2MB of memory. I would like to download additional fonts.

What is the memory allocation for the fonts and what is taken up for the buffer out of the 2MB? When I download three additional fonts, a "not enough memory" message appears.

What can I do to download more fonts?

This article has been archived and is no longer updated by Apple.
Of the 2MB of RAM in a LaserWriter IINT, 616K is used for fonts. Of this amount, approximately 500K is available for downloading additional fonts.

Although there is no memory upgrade for the LaserWriter IINT, you can upgrade it to a LaserWriter IINTX, which can be expanded to 12MB. You can also use the fonts "dynamically" -- which means they are simply placed in the System Folder and the fonts are removed and downloaded dynamically by the operating system.

Lisa: Error 38 is "No Boot File on Disk"

When I try to boot a MacWorks disk on my Lisa, I get an error code 38.

This error is placed under an icon with a check in it. It only accesses the floppy for a brief moment and then gives the error code. It then prompts me to continue or to choose a startup device (STARTUP FROM...). When I continue, the above occurs again, over and over. If I choose a startup device, it gives me the option of the floppy only -- not the HD.

What's going on?

This article has been archived and is no longer updated by Apple.
Error 38 is "No Boot File on Disk." It sounds like the MacWorks disk was erased. If the disk was good to begin with, you have a hardware problem with the floppy drive.

"Macintosh: Error -39 ""End Of File"" Meaning

I am getting a -39 error when I try to open a document. What does the error mean and what might be the problem?

This article has been archived and is no longer updated by Apple.

The -39 error is an "End Of File" error. The most likely cause of the error is a corrupt data file. The only real fix is to restore the data file from a backup or recreate it if there isn't a good backup available.

Apple FORTRAN: Scientific Notation

This article has been archived and is no longer updated by Apple.
To input numbers in scientific notation on the Apple FORTRAN system with both the E and F format specifications, follow this example:

```
10 FORMAT ( E10.2 )
READ (A, 10)
```

When you specify an input field as E10.2, FORTRAN sets aside a field of 10 places, and will put the decimal two places in from the right unless the input string has an explicit decimal point in it.

Another intresting result occurs if you enter the number in scientific notation. FORTRAN reads in the number up to the E and then starts reading the exponent using the next format specification in the FORMAT statement. The example above would use the E10.2 spec for both the mantissa and the exponent.

The string 1.0E1 would be read as 1 times ten raised to ten to the tenth power.
10
10
1 * 10 = 1 followed by 10000000000 zeros.

This, of course, causes an overflow error.

You can get around this problem either by specifying a decimal in the exponent or by padding the input field with spaces. The following example has the entered string in brackets to indicate the extra spaces.

You enter	Fortran interprets
>1.0E1<	10000000.00
>1 E1 <	1.00
>1.0E1.0<	1.00
>1.0E1 <	1.00

Apple II: Wrong Version of Setup Causes Aristotle Problems

I'm having a problem in setting up a lab network using a Macintosh SE/30 as a server, with a combination of Apple IIGS and Apple IIe workstations. I am also using Apple II Setup v2.0.1.

I get the following error message when I try to log on to Aristotle as Administrator from an Apple IIGS: "an error occurred loading the file /volumename/System/System.Setup/Cdev.Init".

When I try using a different startup application (such as BASIC.SYSTEM), I get this message: "Bad OS ver 0011" I'm using version 5.0.2 to install Server Network Startup, and Server Quick Logoff.

Also, I've been getting a System Error when setting up a Macintosh SE/30 as a server and installing System 6.0.3 from the Install menu of the File Server installation disk. Reinstalling System 6.0.5 seems to cure this, however.

This article has been archived and is no longer updated by Apple.
The problem you are seeing with Aristotle is a result of using the wrong version of the Apple II Setup. You have to use Apple II Setup v2.1 or 2.1.1, not v2.0.1, when setting up the software.

As for the problem of installing 6.0.3 from the File Server installation disk, it could be that there is something corrupted in the installation scripts for that version. Nothing you described is a wrong procedure.

AppleShare: Server Maintenance and Backup Questions

What is the best and safest way to operate a file server? AppleShare 2.0 and an Internet router on a Macintosh IIfx.

When I need to install software on the server, I need access to the Server Folder. I have to shut down the server and start up a floppy. This presents a problem, because the Internet router is running -- which disconnects my users from printer access. I know I could move the Router to another unit, but it seems more appropriate to have it on a dedicated unit.

Also, I need to have the database users log off of the databases in order to do a clean backup, so perhaps an automatic backup software package would be better so it could run at night. Also, the backup software selected must be compatible with AppleShare's concurrent software philosophy.

Other than installing software through a remote node, I don't know of any way of installing software on an AppleShare server short of bringing the server down to do it. Secondly, it seems impossible to back up a database that is in use on a server.

This article has been archived and is no longer updated by Apple.
You are correct in your assumptions of the way the system works. To install the software on the server you must bring the system down, which will cause the router to go down. The best time to do network maintenance and upgrades on a large network or on a network that cannot be brought down is at night or on the weekend.

If you back up a database file that is opened, you will not get a proper backup. Any files that are open will not be saved. It is best to do this after hours, also.

There are many backup programs that start at a specified time. That should be the best solution.

AppleTalk PC Card: Code Versions and Compatibility

I want to add some AT&T PCs to my AppleTalk network. I have some old AppleTalk PC cards available (part number M2313). They print all right, but I am worried about conflicts with newer versions of the LaserWriter drivers, etc.

The versions on the PC side are:

* AppleTalk PC DA 1.0
* AppleTalk PC Print driver 1.0
* AppleTalk PC Driver 2.0

Are there newer versions than these, and if so, how can I obtain them on an IBM format disk?
This article has been archived and is no longer updated by Apple.
The cards are the same even though the part numbers are different. The issue is what's bundled with the card. Originally, the card had a utility to handle printing. Then the utility was removed from the package and the card was shipped alone. Then the card was shipped with AppleShare PC, so it has a different finished goods part number. It should be alright to use a more current version of the print driver.

The AppleTalk PC card is now referred to as the LocalTalk PC Card. For more information on this card, please contact Farallon.

TA46653_Apple_II_Workstation_Card_Magic_Slate_Printing_Issue__(TIL08163).pdf

Apple II Workstation Card: Magic Slate Printing Issue (11/96)

When attempting to print from Magic Slate v2.0 using an Apple IIe and a Workstaton Card connected to an ImageWriter II , using AppleTalk, we get the message "includeProcSet IWEm 1 1" on the printout. Is there a fix for this problem?

This article has been archived and is no longer updated by Apple.

Magic Slate thinks it is talking to a LaserWriter instead of an ImageWriter II. Because the Apple II Workstation card emulates a Super Serial Card, you should select that interface in the Magic Slate program.

Also, on an Apple IIe, you always have to run Chooser.II before you run an application and without powering off the computer, see below.

1) Launch your Apple II workstation disk.

2) Choose your printer.

3) Quit Chooser.II, but DO NOT power off.

4) Launch Magic Slate by ProDOS pathname. For example, -/volumename/application name.

5) Configure Magic Slate to print to an ImageWriter at the slot that contains the workstation card.

If this doesn't work, perhaps Magic Slate is not flexible in the slot location or is clearing the Chooser.II info on launch.

Macintosh: Troubleshooting ID=10 Trap Error Bombs

I am repeatedly getting the system bomb "ID=10" on my Macintosh. What does it mean?
This article has been archived and is no longer updated by Apple.
ID=10 is a line 1111 trap error caused by software difficulties. The first thing to do is:

1. Remove all extensions (INITs) and control panels from the System Folder and restart.
2. If you're no longer getting ID bombs, replace the extensions and control panels, one at a time, until you get the error again. The last one put in is likely the cause of the crashes.

If you are still getting the crashes after removing everything, remove the entire System Folder and reinstall a new copy form your System disks using the Installer. If you still get the bombs at this point, determine whether this always happens when using a particular application. If so, replace that application. Also, verify that your application is the most current version available and fully compatible with your Macintosh model.

AppleShare: Slow Startups with CD-ROMs on Network

I have a CD-ROM as a volume on my AppleShare network. I normally shut down the server on Friday afternoons and restart it on Monday morning, leaving it on all week. When I first turn on the server and get the message: "Checking volume 'CD-ROM 4.0' this may take a few minutes", it normally takes anywhere from 15 to 30 minutes for the server to come up. Lately I have seen that message for over two hours and have had to give up and restart the server without the CD-ROM. All the time the message is on the screen, the CD-ROM is being accessed, so the Server isn't locking up.

This article has been archived and is no longer updated by Apple.
The newest version of CD-ROM drivers (3.0.2) speed up access to CD-ROM drives from AppleShare File Servers. Actually, the newer drivers don't let AppleShare do all of the prepping beforehand, and will provide that information on demand at a later time.

LaserWriter II: Printing from DecNet Terminal Server

I'm looking for a product that will allow a DecNet Terminal Server to print to an Apple LaserWriter II.

This article has been archived and is no longer updated by Apple.
If you want to print from a DEC VAX supporting PostScript or from Macintoshes on LocalTalk to a LaserWriter connected to a terminal server port, the following paragraphs may give you some ideas:

Attaching a LaserWriter to a DEC terminal server port is similar to attaching it to the serial port on the VAX. Normally, some steps have to be done by the VAX systems manager to define the terminal server port to be used by the queue manager.

On the Macintosh, you need a cable, with the appropriate pinouts, connecting the LaserWriter to the terminal server port. You have to set the LaserWriter communications settings, such as parity and baud rate, to the same settings as those on the terminal server port. Some installations get by with only 3-pin wiring: transmit, receive, and ground. However, you will lose data when the printer is turned off. You need full modem control port on the terminal server to support all XON/XOFF features.

On the DEC hosts, normally a virtual port is defined for the printer. A command is issued to map the virtual port to the physical port on the terminal server. The physical port on the terminal server should be set as: Accessing mode, Break disabled, Autobaud disabled, and Broadcast disabled. A print queue is then initialized with LATSYM as the name of the processor. PostScript software should be run on the VAX to support PostScript printer queuing. All DEC hosts on the Ethernet with the print queue defined through the terminal server can print to this LaserWriter.

Only the LaserWriter IINTX can be connected to both the serial port and the LocalTalk port and be switchable between them via soft switches. To allow Macintoshes on LocalTalk to print to the LaserWriter on a VAX queue, you may want to look into PacerPrint from Pacer Software.

Desktop Manager: Use Only on an AppleShare Server

I have heard about a file called Desktop Manager, which supposedly speeds up Desktop maintenance over a network and is included with AppleShare in System 6.0 and later. I have also heard that it can be used on any Macintosh, even a single system.

Can this file be used on a single Macintosh to update the Desktop file faster? I don't have AppleShare. Can this file be distributed as a single file with proof of Macintosh ownership? Or can this file be found elsewhere?

This article has been archived and is no longer updated by Apple.
We recommend using the Desktop Manager only on an AppleShare server; we do not recommend its use in any other manner.

The Desktop Manager that comes with the AppleShare File Server software is not to be distributed freely. It is part of the AppleShare File Server software and is covered by the same software licensing agreement that applies to the AppleShare File Server software.

The Desktop Manager contains an INIT that allows the server to handle directory information faster and more efficiently. This file/INIT appears to work properly with most Macintosh system configurations. The Desktop Manager causes problems with the AppleCD SC and has not been officially tested for compatibility with other software.

Macintosh 128K and 512K: SCSI Hard Drives

Can I connect a hard drive to a Macintosh 512K?

This article has been archived and is no longer updated by Apple.
To our knowledge, there is no plug-and-play hard drive for the Macintosh 512K or 128K currently still being manufactured. The Apple HD20, a non-SCSI drive which does work with the 128K and 512K Macintoshes, was made obsolete by the evolution of SCSI devices which brought about Apple's line of SCSI hard drives around the beginning of 1986. SCSI drives require a SCSI port, which is not included with a Macintosh 128, 512K or 512K Enhanced Macintosh. It was first included with the Macintosh Plus. SCSI drives transfer data many times quicker than non-SCSI drives.

In summary, you either need to find a used HD20 non-SCSI drive, or have a SCSI port installed, which would be a third-party product. Dove is one company that makes add-on SCSI ports.

WARNING: Improper installation of these kits may damage the Macintosh logic board beyond service exchangeability.

On AppleLink, you can find contact information on a company mentioned in this article by clicking the "Library Index" button in the lower-center of the Tech Info Library search window, then opening the "Third Party Company Directory" folder.

Softcard III: BDOS Errors

This article has been archived and is no longer updated by Apple.
Sometimes, as a program runs, it drops out with a message BDOS ERROR BREAK IN (various numbers). After this, either the program proceeds after a return or the entire machine is locked up. This happens at infreqent intervals on many other Apple IIIs and other Softcards.

It may seem that the problem is hardware-related, but in fact BDOS ERRORS are usually caused by the CP/M software when it attempts to access a device that is not ready or not on line. In the most common situation, the program tries to read a non-existent disk drive; this reports a BDOS ERROR ON xx: SELECT. Typing a RETURN should return you to the system prompt, and typing an 'R' will retry the last command. The BDOS ERROR BREAK message example above is from MBASIC and refers to the fact that the program attempted to access a device that is not ready or on line; the number in the message is the line number of the MBASIC statement which tried the read. To avoid this message, use the ON ERROR GOTO statement to branch to statements that display instructions to ready the device or put it on line.

Apple IIGS: Using with a MicroNet Hard Drive

I'm having a problem getting an Apple IIGS to talk to a MicroNet SCSI 30MB HD. I have an Apple High-Speed SCSI card, MicroNet HD, and a 1MB Apple IIGS. I also have v2.0 of the High-Speed SCSI Card Utilities.

Although my Apple II SCSI Utilities see the HD, I can't get GS/OS (v5.0.2) to see the drive.

This article has been archived and is no longer updated by Apple.
Assuming the hard drive is compatible with the Apple IIGS (check with MicroNet) here's what you need to do:

Make a new bootable System Tools disk, using the Installer from the SCSI utilities disk, and specifically install the SCSI driver from the new utilities disk that came with the SCSI card. This makes the disk realize there is a SCSI device attached. As the system starts up, it looks for SCSI devices and if it finds one that should be readable but is not, it will then ask if you want to initialize.

Make sure the slot the SCSI card is installed in is properly set in the Control Panel. (That slot should say "your card".)

LaserWriter: Driver Versions and Macintosh System Versions

I'm told that LaserWriter Driver 6.0 is associated with System 6.0.4. LaserWriter Driver 6.0.1 comes with System 6.0.5.

Can you use LaserWriter Driver 6.0.1 with System 6.0.4? If not, why? What about using LaserWriter Driver 6.0 with System 6.0.5?

If one Macintosh on an AppleTalk network is running LaserWriter Driver 6.0 and another is running Driver 6.0.1, will the LaserWriter be re-initialized each time one Macintosh goes to print after the other has just printed? (For instance, if one Macintosh was using Driver 5.2 and another was using Driver 6.x.x.)

This article has been archived and is no longer updated by Apple.
The LaserWriter will reinitialize if it sees someone trying to print with a different version of LaserWriter and Laser Prep, regardless of the size of the difference in version numbers.

The drivers are not truly "associated" with a particular system release, they just happen to be distributed with that release. You can use 6.0.1 LaserWriter and LaserWriter Prep with System 6.0.2 if you like, just as you can use version 5.2 LaserWriter and LaserWriter Prep with System 6.0.5.

Use the suggested print driver that is best for the software, and standardize the whole network on that version to avoid loss of time due to reinitialization of the printers.

Macintosh LC: Apple IIe Card Enables Network Printing

If I connect several Macintosh LC computers via LocalTalk connector kits and have a couple of ImageWriter printers attached, will the software recognize the printer location when using the Apple IIe emulation card?

Specifically, most standalone software for the Apple IIe looks for slot 1 to print. If I use the LocalTalk option card in the ImageWriter and connect up via LocalTalk, will it recognize the placement of the printers? Will I be able to print using the Apple IIe Card and Apple IIe software under this scenario?

This article has been archived and is no longer updated by Apple.
When using the Apple IIe card in the Macintosh LC, you can print to serial devices using PR#1, and print to LaserWriters and ImageWriters on a LocalTalk network.

Published Date: Feb 18, 2012

Macintosh: How To Tell if You Have a Coprocessor Installed

How can I tell if my Macintosh has a coprocessor installed?

This article has been archived and is no longer updated by Apple.
If you want to know if you have an adapter (with a coprocessor) installed in your Macintosh without checking the computer physically, you need to use a software utility: nothing in the Macintosh operating system gives you this information.

There are several shareware CDEVs that report system configuration, as well as many disk and file utilities, such as SUM II and MacTest. Also, some applications (Microsoft Excel is one) report the presence of a coprocessor.

AppleShare: Installing on Macintosh IIfx/IIci

I'm about to install AppleShare on a Macintosh IIfx. I've heard that AppleShare requires some 'patches' for the Macintosh IIfx. Is that true?

This article has been archived and is no longer updated by Apple.
There's only one hitch to installing AppleShare on a Macintosh IIfx or Macintosh IIci: You need to use the Network Products Installer diskette to perform the actual installation, rather than the Installer that comes with AppleShare.

The operating system version on the AppleShare Installer diskette is too low to run on the Macintosh IIfx; the Installer on the NPI diskette is 6.0.5 (which will run), and it includes the necessary scripts to install AppleShare File Server, Print Server, Internet Router, EtherTalk, and TokenTalk.

You will still need to have the original File/Print Server (or whichever) diskettes handy, as the NPI has only the scripts, not the actual programs.

Macintosh: Troubleshooting Error -42 "tmfoErr"

My Macintosh keeps getting the "Error in printing this document -42". I'm using background printing under MultiFinder printing a Microsoft Works document. My Macintosh is running System 6.0.8.
This article has been archived and is no longer updated by Apple.
Error -42 is tmfoErr, or a "too many files open" error. You might have reached the default maximum number of files that can be open at any one time.

During our testing of Microsoft Excel, when we reached the maximum number of open files allowed on our system (40), we couldn't create a print job nor open any other files. We got a variety of error messages: Print Monitor error, "file is damaged" error, or a Print Manager error, and "Error Printing on LaserWriter (driver version) you are using". Other programs that we tried to open trapped the system error and reported it differently.

Many programs open numerous files when launching, so you might want to investigate what you have open at the time of the error if this scenario fits.

If you are **not** encountering the maximum number of open files limit, you might have a directory fault. Try running Disk First Aid (or a similar program), or reinitialize and reinstall the software on the hard disk to see if this corrects the situation.

Softcard III: Using CP/M with a Profile

This article has been archived and is no longer updated by Apple.
The Softcard III Installation manual recommends on page 83 that a user allocate 3200 SOS BLOCKS into two CP/M volumes (each 1600 blocks) when setting up ProFile. This will give the user approximately 792K in each CP/M volume. These blocks are on the ProFile and in no way effect the size of the transient program area (TPA). The TPA is fixed by the implementor (Apple) and cannot be changed. The size of the TPA is defined as the memory range from 0100H to the bottom of the BDOS (0CC00H), which works out to 50.75K (51,960 Bytes). Note that the TPA includes the area of memory used by the CCP (2K). Application programs may overwrite the CCP and use the 2K of memory, but must exit back to the CP/M system via a Warm Boot (which reloads the CCP).

Remember that SOS device drivers reside outside of the CP/M environment and therefore have no effect on the size of CP/M. CP/M takes up 56K in the Apple III because of the amount of BIOS code required to interface to device drivers.

Use 2060 blocks for each CP/M volume on the ProFile. This works out to 1 Meg of user space (exlcuding directory) for each volume. We highly recommend that you use the updated version of the CP/M Boot & BIOS code, version 2.21.

GIFF-to-PICT Conversion: Reduced Resolution Is Lost Lookup Table

Why is it that when you convert a 256 color GIFF-formatted graphics file to a PICT file, the image quality is worse (the color mapping is off)?

I've been downloading graphic GIFF files from a variety of public bulletin boards and on-line information services. I want to import these graphic images into Macintosh programs that support PICT files, using such Macintosh programs as PICTureThis and Giffer to convert GIFF files to PICT files.

Invariably, the converted PICT image is worse in image quality than the original GIFF image that is displayed on the Macintosh screen using Giffer. It appears that the colors used in the original GIFF image don't completely map to the colors displayed in the PICT image.
This article has been archived and is no longer updated by Apple.
It may be that the color lookup table is being lost. The GIFF file has its own custom lookup table that is either not being converted to the PICT file, or the program used to display the PICT file is not using the custom lookup table.

Contact the vendors of the utilities you are using to see if they know of a workaround.

AppleWorks GS: How to Print Foreign Characters

On an Apple IIGS, why can't I print foreign characters from AppleWorks GS to a LaserWriter?
This article has been archived and is no longer updated by Apple.
The Chooser II application in ProDOS supports only the standard character set. It doesn't print foreign characters displayed on the screen. With AppleWorks GS, anything other than Draft will print as a bitmapped version of what is displayed on the screen. This allows you to print foreign characters.

The only other option is to get an application that supports foreign languages. For more information, search on "Claris".

Macintosh IIci Built-in Video: RAM Should Be Installed in Bank A

My Macintosh IIci won't start up when a monochrome monitor is attached to the on-board video port. At first I thought it was a memory problem, so I replaced all four 256K SIMMs -- that didn't help.

Then I found that if I unplug the monitor it starts up fine. I have installed the Macintosh II video card and it works fine.

Will the Macintosh IIci internal video port work with only 1MB of RAM installed?

This article has been archived and is no longer updated by Apple.
The Macintosh IIci's built-in video will function with only 1MB of RAM, provided that the RAM is located in Bank A. You will only be able to select monochrome display in the Monitors CDEV. If the RAM is in Bank B, then the Macintosh IIci ignores the video port entirely.

Published Date: Feb 18, 2012

Macintosh IIfx Upgrade: Some Symptoms of Bad RAM

I upgraded my Macintosh II to a Macintosh IIfx by purchasing the Macintosh IIfx logic board upgrade and two 4MB Macintosh IIfx memory upgrades.

This is actually the second logic board that I've ordered. The first was returned to Apple because it had the multichime error sound when first turned on with the full 8MB of RAM. However, it worked properly with only 4MB installed.

The second logic board has a similar problem. If 8MB of RAM is installed, the unit acts strangely. Here are some symptoms:

* The desktop is extremely slow to update at startup, particularly when it tries to read the hard drive.

* When an icon is moved, multiple remnants of the icon are left behind on the desktop.

* Inserting a locked, known good floppy disk into the drive causes a dialog "Disk is damaged and can't be used". Reinserting the same disk into a Macintosh IIci or Macintosh SE results in normal response.

* The system has trouble launching programs and eventually crashes with a system error = 03 or 10 error.

* Disks that were not write-protected were permanently damaged and could not be repaired with Norton Utilities for the Mac. When opened on any other system, the disk would indicate that it had used space, but no icons appeared.

* Disks inserted would often be missing several icons. When those same disks are inserted into other systems or this system running 4MB, all icons appear.

The interesting thing is that if the machine is reduced to 4MB of RAM populated in bank A, it works just fine. It doesn't matter which RAM chips are placed in Bank A -- as long as Bank B is empty, the system is normal.

This article has been archived and is no longer updated by Apple.
We have heard of this problem before. It turned out to be bad RAM causing the crashes and erratic behavior. Replace the memory in the back bank with four new SIMMs of a different brand.

Macintosh Volume Drag-Copy: Why Installer May Be Needed

If I completely drag-copy an entire mass-storage volume, including the System Folder, to another volume, do I still need to use the Installer to rewrite the System on the target volume?

This article has been archived and is no longer updated by Apple.

Various Macintosh models have slightly different ROM codes. The Installer determines which model it is installing to, and installs the appropriate ROM patches for each model.

If you have already run the Installer on a volume and you want to transfer that System to another volume that will be used on the same or similar computer, it should be alright.

Also, if you do a customized install, and choose "System Software for any Macintosh", it should be alright using that volume on different Macintosh models.

LaserWriter IINTX: LaserJet Compatibility and Bitmapped Fonts

I have a Macintosh/DOS cluster running under TOPS with a LaserWriter IINTX as a common printer. The TOPS system is the latest versions. The LaserWriter IINTX is being set up as a LaserJet Plus as described in the manual.

The output from the DOS software is ragged and poorly defined. The resolution looks like it came from a dot-matrix printer (72 dpi).

If the software output is printed to a direct HP LaserJet, the quality of the output is just what I want (300 dpi).

My questions:

1) How fully does the LaserWriter IINTX emulate the LaserJet Plus? Is the compatibility only 80-85%, or will the LaserWriter IINTX fully become a LaserJet?

2) Is there a limit to the number of times the printer can be reset (resetting from a LaserWriter mode to a LaserJet mode)?

This article has been archived and is no longer updated by Apple.

1) Adobe Systems has performed tests comparing LaserWriter IINTX and LaserJet Plus. Their finding is that a LaserWriter IINTX in LaserJet Plus emulation mode is generally faster than a LaserJet Plus, and is more than 95% compatible. The newer ROMs in the LaserWriter IINTX will increase compatibility even more.

The LaserWriter IINTX in LaserJet emulation does not fully support LaserJet bitmapped fonts, but does support PostScript fonts. This may explain your problems with the "jagged" output, if you're using LaserJet bitmapped fonts.

2) The minimum number of "switches" is 100,000, if all performed via software. We don't have the number for the DIP switches, as there are too many variables to take into account.

Macintosh IIci: Does Not Use VRAM

Is 512K VRAM available on the Macintosh IIci?

This article has been archived and is no longer updated by Apple.
The Macintosh IIci does not use VRAM (video RAM), nor can be expanded with VRAM. The computer uses main system RAM from Bank A of the logic board.

If there is at least 2MB of RAM on the logic board, you will be able to access the maximum pixel depth for the attached monitor: for a High-Resolution RGB Monitor set to 256 colors, that amounts to 384K of RAM taken for video.

HyperCard: How To Hide Its Title Bar on External Monitor

I am doing a presentation and want to hide HyperCard's title bar so it doesn't appear that I am in HyperCard.
This article has been archived and is no longer updated by Apple.
When HyperCard is run on a Macintosh with a display larger than nine inches (basically, any Macintosh with an external monitor), a title bar normally appears at the top of the HyperCard window. It's possible to make this title bar invisible (on a color system), and it's also possible to eliminate it entirely.

* Making the Window Title Bar Invisible

Making the title bar invisible is the safer method, because the changes you make can easily be undone. And although the title bar is invisible, it's still there and can be dragged. However, this method works only in color, and in color you lose HyperCard's visual effects.

Here's how to set the Desktop, and the window title bar and its components, to the same color -- making the title bar invisible:

1. Put the cdev called Kolor (Kolor is available on bulletin boards) in your System Folder.

2. Open the Control Panel, then click on the cdev named General.

3. Click on the dark blue color where it says "Desktop Pattern."

4. Color in the box above the word "Desktop" so it is solid blue.

5. Double click on the dark blue color. A window will appear with a color wheel. Write down the values in the Red, Green, and Blue fields.

6. Click on the cdev Kolor.

7. In the window title bar section, click on the "Title text" square. This will bring up the color wheel again.

8. Change the values in the Red, Green, and Blue fields to match the numbers you wrote down in step 5.

9. Repeat steps 7 and 8 for the "Lines/boxes," "Border," and "Title bar" squares.

Your title bars now appear to be invisible when shown against the Desktop Pattern.

* Eliminating the Window Title Bar

Eliminating the title bar actually changes the window structure. It has nothing to do with color, so it has effect on large-screen monochrome systems as well as color systems. This procedure changes HyperCard itself, so back up HyperCard first. The information here is given for versions through 1.2 of HyperCard.

1. Use a file editor such as Fedit Plus to open the HyperCard application.

2. Do a search for one of the following hexadecimal strings:

HyperCard 1.01: 05A0 2F3C 0004
HyperCard 1.1: 05DC 2F3C 0004
HyperCard 1.2: 0638 2F3C 0004

which should occur only once in the HyperCard file.

3. Change the last character of this string from 4 to 2.

4. Save the change and exit the file editor.

5. When you run HyperCard, the window will no longer show the title bar.

If you need to restore the window title bar, use the file editor to change the 2 back to 4. The parameter that was changed is passed to the Toolbox Window Manager call NewWindow. The value 4 tells NewWindow to draw a document window (with title bar) without a grow box. The value 2 tells NewWindow to draw a plain box without a menu title bar.

Apple Scanner: Troubleshooting SCSI Problems

When using an Apple Scanner with my Macintosh SE/30, I keep getting a message about not being able to find any device attached to the SCSI port. I checked the SCSI number to make sure we did not have any conflicts, made sure there was a terminator attached properly, checked the cable itself, and reinstalled the AppleScan software. The serial port is working fine.

The hard drive in the Macintosh SE/30 doesn't always start up the first time the computer is turned on. My dealer said that the hard drive may be the cause of the problem, and that I may need to replace a chip on the I/O board.

This article has been archived and is no longer updated by Apple.
This type of problem is usually a SCSI termination problem that originates in the drive or the scanner. The problem could be with the hard drive, but not with the PROM that needs replacing. (Note: This service program is for replacement of a chip of the drive, not the drive itself.)

First try moving the terminator to another location. If the terminator is on the end of your cable, move it to the scanner's empty SCSI port. If it's on the empty port, move it to the end of the cable. If this doesn't do anything, try removing the terminator completely.

Next, check the scanner to confirm that its internal terminators have been removed. Finally, try using a different hard drive.

LaserWriter IINTX: Can Use Some Macintosh SIMMs

Can I use Macintosh IIfx 4MB SIMMs in a LaserWriter IINTX?

This article has been archived and is no longer updated by Apple.
The LaserWriter IINTX accepts only 256K and 1MB SIMMs. Macintosh IIfx 1MB SIMM modules can be used in the LaserWriter IINTX, but not the other way around.

Published Date: Feb 18, 2012

Macintosh: SIMM Speed Configurations

Can I mix and match SIMM speeds when upgrading memory on my Macintosh?

This article has been archived and is no longer updated by Apple.

As a general rule, SIMM speeds should match within a bank, can be different between banks, and all must be compatible for the specific Macintosh model. In other words, as long as all the SIMMs in Bank A match in speed, all the SIMMs in Bank B match, and all the SIMMs in the system meet the refresh speed specification, you should have no problem.

AppleShare Print Spooler: Ways to Speed Performance

?

I'm currently running an AppleShare Print Spooler on a Macintosh Plus with an external HD20. Would the speed and throughput of the spooler be increased if I upgraded it to a faster Macintosh or if I added more memory to my Macintosh Plus?

This article has been archived and is no longer updated by Apple.
Anything EXCEPT memory would increase the performance of your spooler. RAM performance improvements are incremental, but usually not enough to justify the cost of the RAM. This depends on how many utilities you may have running on your server, but if you're running a stripped-down server, you don't really need more memory.

Here are the items that will most improve the performance of your server:
* Cabling type (using Ethernet instead of LocalTalk)
* Getting a faster computer
* Getting a faster hard drive

We can't really provide any hard statistics on performance because there are far too many variables and that change from moment to moment during network use.

TA46686_Apple_IIe_Utility_for_Partitioning_Hard_Drives_(TIL08200).pdf

Apple IIe: Utility for Partitioning Hard Drives

I want to add a high-speed SCSI card and a 85MB hard drive to my Apple IIe. Is there a ProDOS utility that can partition such a large drive?

This article has been archived and is no longer updated by Apple.
The utilities disk that comes with the high-speed SCSI card can handle the partitioning. The only problem is that the Apple IIe can only see two partitions of 32MB each. So, only 64MB of the disk will be used; the rest of the space will be inaccessible.

The only other option is to search for a third party solution.

Apple IIGS: 25-Inch Monitor Not Recommended

Is there a way to hook-up an Apple IIGS to a 25-inch monitor?

This article has been archived and is no longer updated by Apple.
Because the Apple IIGS only supports up to 640 x 200 pixel resolution (with no optional video cards available) we don't recommend adding a large screen monitor.

All you would accomplish in any case is magnifying the screen -- no desktop space would be added. Also, the enlarged screen would look grainy.

Macintosh XL: Connecting to a LaserWriter (10/94)

How do I connect a LaserWriter to my Macintosh XL?

This article has been archived and is no longer updated by Apple.
The Macintosh XL has AppleTalk built into the ROM so you can print to the LaserWriter as you would from a Macintosh 512k. You need a DB-25 LocalTalk cable to connect to the Macintosh XL's serial port.

Once you have the cabling connected between the Macintosh XL and the LaserWriter, make sure the LaserWriters mode switch is set for "AppleTalk", use the Control Panel to make AppleTalk active, and then use Chooser to select the LaserWriter.

Here are the pinouts needed to make an adapter from a Macintosh AppleTalk Connection Module (DB-9) to a Macintosh XL connector (DB-25).

Macintosh DB-9 Female	Macintosh XL DB-25 Male	Signal Mnemonic
8	19	RXD+
4	20	TXD+
9	3	RXD-
5	2	TXD-
SHIELD	SHIELD	GND

A word of caution is necessary. Because there are signal losses in cables longer than 18 inches, the AppleTalk Connection Module cable is supposed to be no longer than 18 inches, and the modules are constructed with an 18-inch cable already on them. There is a risk in connecting an adapter from the module to the Macintosh XL because the extra cable in the adapter might create signal losses that result in erratic operation of the Macintosh XL node. To minimize this risk, make the adapter's wiring as short as possible.

CAUTION! To avoid FCC Class B signal violation, this cable should be fully shielded, as the data is at a very high rate and is not attenuated by the connection boxes normally used in AppleTalk.

LaserWriter IINTX: Attached Drives Must Give Capacity Info

Can a SyQuest removable media SCSI drive be used as a SCSI device on the LaserWriter IINTX?

This article has been archived and is no longer updated by Apple.
The only limiting factor, and this holds true for all SCSI drives when attached to the LaserWriter IINTX, is that the drive must relay information on its capacity back to the LaserWriter. This information allows the LaserWriter controller to determine how much disk space is available for caching and storage and reports this info back to the LaserWriter Font Utility.

You'll need to get clarification from the drive manufacturer most likely.

X.25 Protocol: Using It With InterBridges

This article has been archived and is no longer updated by Apple.

The Question

Suppose you want to connect to a network based on the X.25 protocol. You may want to connect an InterBridge to their backbone zone, then connect the InterBridge via one of its modem ports to one of the ports on an X.25 pad located in the WHTC complex. The connection is to tie into another AppleTalk network that has been connected in a similar fashion at some other point in the X.25 network. Your concerns are:

- how to initiate the connection between two InterBridges across the X.25 bridge.

- the amount and size of packet traffic generated by two InterBridges polling each other's existence across the X.25 bridge.

Making the Connection

To initiate the communication between bridges, just turn on the InterBridge. It then polls the nearest bridge and updates its internal table of zones available on the net from the adjacent InterBridge. It also passes its zone address number and name to the other bridge. If a bridge is turned off, it will rebuild the zone table at power on. After a delay in rebuilding the table, it maintains the table on its own. Applications such as the Chooser and InBox, which communicate over AppleTalk, can request the zone information from the InterBridge. Bridges periodically update their tables and will, upon receiving a new zone address or a packet referencing an unnamed zone address with a name, will update the table to reflect the new zone address and zone name.

There is one consideration that may cause some applications not to function with this network. Because InterBridges use ZIP, which is "best effort" protocol, checking for timeouts or proper data handling must be handled by the application. Some applications, notably AlisaTalk running on a VAX, will time-out if delays are very long across the network. You are then at the mercy of whatever traffic and traffic problems might exist on the X.25 net.

Packet Traffic

During the first 30 seconds of polling time, approximately 5-6 packets are transferred between InterBridges. These packets are in ZIP (Zone Information Protocol). The first will be a ZIP bringup packet that will be delivered out each of the connected ports. This is followed by a ZIP GetZoneList or GetMyZone packet. The GetZoneList packet is replied with a GetZoneList Reply packet. The new InterBridge might send a ZIP Query for information on packets whose addresses are not yet in its Zone Information Table (ZIT). This also will be replied and will be in the form of a ZIP reply packet.

The packets range in size: 8 bytes for a ZIP GetZoneList, 45 bytes for a ZIP bringup, 13 bytes plus 32 bytes for each zonename for a ZIP reply packet, and for a GetZoneList Reply there would be 9 bytes and 32 bytes for each zone name.

The first group of bytes contain the LAP (Link Access Protocol) header, the DDP Datagram Delivery Protocol) header, and the ZIP (Zone Information Protocol) header. This will be true for takedown, bringup, query, and reply packets. The ZIP GetzoneList and GetZoneList Reply packets use ATP (AppleTalk Transaction Protocol) header and user bytes. These transactions take place with each connected port.

There are two AppleTalk ports and two Serial ports on the InterBridge. After

the initial polling, one packet each 10 seconds is transmitted to maintain the connection while idling.

Macintosh Display Card 48: Color Problems

I have a Macintosh with a two page monochrome monitor and a Macintosh Display Card 4*8 video card.

When the control panel has the card set to black-and-white, the monitor drops pixels at random. When the card is set for four shades or 16 shades it works fine.

Is this normal, or should I replace the card?

This article has been archived and is no longer updated by Apple.
That is most definitely NOT the normal function of that video card -- we would recommend replacing it, as the video memory is probably damaged. In fact, you may be able to see slight discolorations (when the monitor is in color mode) in the upper-left corner of the screen because of RAM failure. Even if you don't see the discolorations, we would advise replacing the video card anyway.

TA46708_Apple_III_Keyboard_layout_(TIL00823).pdf

Apple III: Keyboard layout

This article has been archived and is no longer updated by Apple.
Applications in development often require a particular keyboard layout. There are some problems during the creation of this file because the standard drivers manual doesn't provide enough information about the internal organization of a keyboard layout file. The easiest way to change the layout is to modify an existing keyboard file. The file is laid out in the order of the table on page 136-137 of the Apple III Standard Device Drivers manual. For example, the first eight bytes of the SHOLES layout are:

31 21 32 21 32 40 32 00
1 ! 2 ! 2 @ 2 NUL

The four values, as presented in the table in the manual, are in the order:
Alone, SHIFT, CONTROL, Both.

Laser Fonts: Corrupted Font Problems

I'm experiencing an intermittent problem when using the font "Times 12".

It sometimes does not use the whole line. No characters are lost; it simply prints the rest of the line on the next line.

Some documents do work, others don't. Generally if I take a file that does not work and either change the font style or size, it prints correctly. I tried re-installing the fonts with no success. I've taken the "bad" file and printed it on another computer and laser printer and it works!

This article has been archived and is no longer updated by Apple.
This type of problem is usually caused by a corrupt font installed in the System; we would recommend at least replacing the font with Font/DA Mover, if not trashing and reinstalling the operating system with Installer.

If the problem persists, try reloading the application from diskette.

TA46716_Macintosh_IIsi_Logic_Board_ROM_Slot_is_for_Upgrades_(TIL08239).pdf

Macintosh IIsi: Logic Board ROM Slot is for Upgrades

Some Macintosh IIsi computers have a slot and a board next to the NuBus/030 expansion slot. I can't find any information about the slot in the manuals or recent magazines.

This article has been archived and is no longer updated by Apple.
The ROM SIMM slot is for upgrading Macintosh IIsi ROMs. There are actually two versions of the logic board being shipped as of December 1990: One type has the ROM surface-mounted to the logic board; the other does not have this ROM at all (only a space for it) but does have the SIMM installed.

The rule-of-thumb for the ROM SIMM: If a board has it, don't remove it; if it doesn't, don't put one in.

Apple FORTRAN: Complex Numbers and Character String Functions

This article has been archived and is no longer updated by Apple.
In learning FORTRAN, you sometimes have to simulate complex number functions without actually using CMPLX(A,B) (which takes the real number A and the imaginary number B and returns the complex number result) or AIMAG(A) (which returns the imaginary part of the complex number A). REAL Fortran77 brings an easy solution: use character strings and simple arithmetic, treating the real and imaginary parts of the complex numbers separately. Alas, the designers of Apple FORTRAN chose not to include the character string functions and procedures.

The following hints at a solution; an end-user wanted to print character strings in the graphics page using WSTRING(string), which also wasn't implimented.

The small assembly language function below returns the ascii value of the nth character of a string. Frustrated Apple FORTRAN programmers will find this useful.

For the complex function other such routines might need to be written; a length-of-string and an index function would be very helpful.

```
;
; Function CHAR1 (string,N)
;
; returns ASCII value of Nth character in string
;
; William B. Judd, TRI, 10/27/83

Macintosh Portable: What Monitors can be Attached

What monitors can be connected to the Macintosh Portable's monitor port?

This article has been archived and is no longer updated by Apple.
The Macintosh Portable needs a monitor adapter to connect a monitor to its video port. Various third party adapters are available.

For more information, search under "Portable" and "video".

TA46720_Apple_Printers_How_To_Print_KanjiTalk_Documents_(TIL08244).pdf

Apple Printers: How To Print KanjiTalk Documents

Article Change History

09/16/92 - UPDATED
* To include information on locating Kanji resellers.

If I'm using Kanji Talk and a Japanese word processing package, such as Kanji Word, do I need to make any special modifications to print to a LaserWriter?

This article has been archived and is no longer updated by Apple.
You'll need an Apple LaserWriter IINTX-J, a Kanji-compatible LaserWriter, which is available in Japan as well as a limited but growing number of resellers in the United States. You can call 1-800-882-8856 to find a reseller in your area.

You can also use Kanji TrueType or ATM-J with any QuickDraw printer, such as a StyleWriter or Personal LaserWriter LS.

TA46721_Apple_IIGS_Memory_Requirements_for_an_AppleShare_Network_(TIL08245).pdf

Apple IIGS: Memory Requirements for an AppleShare Network

?I have Apple IIGS computers (ROM version 01, 512K RAM) on an AppleShare network. When I try to logon to the server from a workstation, I get garbage on the screen that looks like:
2.1(GS/OS)
00/1179: 00 00 BRK00
A=0201 X=01E0 Y=000E S01E2 D=0000 P=01
B=00 K=00 m=0c Q=9E L=1 m=0 x=0 e=0

This occurs about half way through the login process (thermometer bar half way across).

The settings are correct according to the manual (Slot 1 = Your card, Slot 7 = AppleTalk, Startup Slot = 7). My RAM disk is set for 256 Minimum, 256 maximum its only possible setting).

The one Apple IIGS that logs on without a problem has ROM version 3 and 1MB of RAM.

This article has been archived and is no longer updated by Apple.
Your Apple IIGS computers don't have enough memory: they require 768k to run. Check your memory expansion cards and verify that they don't have more than eight chips on the cards.

Published Date: Feb 18, 2012

ImageWriter II: Problems Feeding Form Paper

My ImageWriter II's four-page form paper is falling out of the sprockets when feeding. I tried cleaning the platen and the bottom guide.
This article has been archived and is no longer updated by Apple.
Assuming you're not using both the friction and manual feed settings simultaneously, there's really only one adjustment you can make: Reset the clear plastic paper guide that mounts on the ribbon carriage assembly.

The rule of thumb is: Loosen the paper guide and put your four-part form **and** one additional piece of paper through the printer. Press the paper guide up to the mass of paper--not too tight--and tighten the guide's screws. This gives the proper clearance for the four-part form plus a slight amount for margin-of-error. You may also have to run your forms with the paper bail up (not riding the platen).

TA46723_Apple_IIGS_Daisy_Chaining_DuoDisks_(TIL08247).pdf

Apple IIGS: Daisy Chaining DuoDisks

My Apple IIGS has a 3.5-inch drive plugged in to the internal port. Can I daisy-chain a DuoDisk off the 3.5-inch drive or does the DuoDisk need its own separate controller in slot 6?

This article has been archived and is no longer updated by Apple.
Older Apple IIGS computers (ROM 01), you can connect the DuoDisk directly to the SmartPort or to a drive attached to the SmartPort.

Newer Apple IIGS computers (ROM 03) need a DuoDisk interface card.

Macintosh Portable: Number of Times Battery can be Discharged

How many times can a Macintosh Portable's battery be completely discharged before it no longer holds a charge?

This article has been archived and is no longer updated by Apple.

Just one complete discharge of the Macintosh Portable's lead acid battery can damage the battery's cells to the point where it could no longer hold a charge.

Published Date: Feb 18, 2012

Macintosh: Error -61 "Write Permissions Error"

Using a Macintosh IIsi and System 6.0.7, I keep getting an error -61 when playing sound in the Control Panel, especially when recording and saving sound files.

This article has been archived and is no longer updated by Apple.
A -61 error is a "Write Permissions Error" where the Macintosh System is keeping the active application from making changes to a file or directory structure. If the problem is occurring in the Control Panel, this suggests a locked file somewhere in the System Folder (basically, no System file should ever be locked) or a corrupt Desktop.

If all of the System files are unlocked and the problem persists, we recommend trashing and reinstalling the System Folder using the Installer on your system disks.

Published Date: Feb 18, 2012

RPS REBUILD: File Access Structure

In the following situations, the FAS (File Access Structure) was set up incorrectly for the rebuild.
This article has been archived and is no longer updated by Apple.
1. At an error -1406 (Index file is damaged), the RPS Damage Report showed Index corrupted as TRUE.

The RPS REBUILD gave error -1520 (No duplicate key allowed). The key was set up as No duplicates allowed. Therefore the file was inaccessible and couldn't be repaired.

2. A file with 13 records was set up the same way as the damaged file (making sure there were no duplicate keys). The RPS REBUILD gave the same error.

To correct the problem, you would have to Consult the FAS in the program that created the file.

Apple SuperDrive: Troubleshooting Upgrade Problems

I have a Macintosh II system with two 800K drives. I installed a SuperDrive but the SuperDrive would not recognize 1.4 MB disks. When a high-density disk was inserted in the new drive, the computer said that it was unreadable and wanted to initialize it which failed.

I tried a different SuperDrive, but I get the same results. Which steps did I miss?
This article has been archived and is no longer updated by Apple.
The FDHD Upgrade Kit included the 1.4 MB FDHD SuperDrive, four ROM replacement chips to replace the older ROM version four chip set, and one SWIM chip to replace the IWM chip. All five chips must be replaced to recognize the SuperDrive. After upgrading the ROMs and SWIM, install System 6.0.2 or higher to support the SuperDrive.

The Macintosh IIx logic board supports the SuperDrive and does not require an upgrade.

The ROM part numbers are:

- 342-0639
- 342-0640
- 342-0641
- 342-0642

Note: This upgrade has been discontinued.

Display Card 824: How to output NTSC without a converter

Can the Macintosh Display Card 8*24 be used to display images from the Macintosh on a video display or a TV without an NTSC converter?

This article has been archived and is no longer updated by Apple.
The Display Cards 8*24 and 8*24 GC do not use software for switching to the NTSC interlaced mode. To put the Display Card 8*24 into the NTSC mode, a properly configured cable is all that is required. Most NTSC devices use an RCA-type phono-connector, so this diagram uses that as a reference point.

Adjust the phono-connector side to whatever type of connector is used. "Tip" is the pin in the center of the connector (the signal); the sleeve is flanged around the outer edges of the connector (the chassis ground).

Card Connector RCA-Type Phono-Connector
---------- ----------
4 MON.ID1 (sense0) --|
7 MON.ID2 (sense1) --|
11 C&VSYNC.GND --------|

5 GRN.VID ----------> Tip (signal)
Shell CHASSIS.GND ----------> Sleeve (ground)

By grounding pin 4 and pin 7 to pin 11, the video cards are told that an interlaced (NTSC) monitor is attached. The actual black and white video signal is on pin 5 and connects to the center (Tip) of the phono-plug. The shell of the card connector connects to the sleeve of the phono-plug.

To acquire a color NTSC signal from any Apple Macintosh display card, an RGB-to-NTSC converter is required.

For more information, search under "NTSC video encoding".

System 7: Background Printing and PageMaker

I want to use background printing with PageMaker 4.0. PageMaker normally uses the Aldus drivers, which don't use PrintMonitor. Is there a way I can do this?
This article has been archived and is no longer updated by Apple.
You can use the Apple LaserWriter driver by holding down the Option key,selecting Print from the menu, and then clicking the Print button. This uses the Apple driver instead of the APD. The next dialog will be the standard Apple LaserWriter 7.0 Page Setup dialog followed by the Apple LaserWriter 7.0 print dialog. If background printing has been turned on in the Chooser, it should work, but may not. Aldus Technical Support provided this information.

There are other reasons for selecting the Apple driver instead of the Aldus driver. Apple drivers will print PICT files better, whereas the APD prints TIFF and PostScript better.

Version 4.2 of PageMaker is System 7 savvy. The Aldus print drivers can take advantage of background printing unlike the prior versions.

ProDOS: Problems using the CONVERT program in 80 columns

The CONVERT program malfunctions if it is executed when the 80 column display is active. The top lines are scrambled and ProDOS date and prefix aren't displayed.
This article has been archived and is no longer updated by Apple.
Here are two possible workarounds:

1. Exit from the 80-column card firmware with ESC-CTRL-Q, then execute CONVERT.
2. Enable 40-column display with ESC-4, then execute CONVERT.

In both cases you restore the 40-column screen, and the program works correctly.

This situation occurs in the following configuration:

1. ProDOS Developer's Disk V 1.0 C
2. ProDOS system file dtd 01.11.83
3. Convert program version 1.1, dated 01.11.83
4. System configuration: Apple IIe and Extended 80-column card.

SOS: Error messages

This article has been archived and is no longer updated by Apple.
Here are some Pascal III I/O errors reported (in Volume 2 of the programmer's manual) as SOS errors and which cannot be found in the SOS Apple Technical Communications Manual. The remarks are general and made without knowing the circumstances, applications or languages involved.

36: Device not available = SOS error $24
Error $24 means that a device like a printer is not on-line, although a driver that will return this error is not known.

44: Invalid byte count = SOS error $2C
Error $2C means that a SOS call from an application didn't have the appropriate parameter list for the call.

45: Invalid block number = SOS error $2D
Error $2D means that the application is asking for a block past the end of the disk. This has occurred with System Utilities. There the problem is that some program, perhaps Apple Writer, changes the directory or index blocks on the disk so that the file points off the end.

TA46743_Macintosh_Video_Digitizers_(TIL08286).pdf

Macintosh: Video Digitizers

This article describes two video digitizers available for the Macintosh.

This article has been archived and is no longer updated by Apple.

MacVision 2.0

MacVision 2.0 Video digitizer, from Koala Technologies, offers 256 shades of gray and 640 x 480 resolution. It runs on a 512K or later Macintosh.

MacVision allows a user to put digitized pictures and graphics into a Macintosh, or take video images from a VCR or laserdisc player.

Here are the features of MacVision:
* Accepts any video source
* Images both flat and three-dimensional objects
* Ten different scanning techniques
* Compatible with all major software
* Works as both a desk accessory and a desktop application

ComputerEyes

ComputerEyes Video digitizer, from Digital Vision, Inc., runs on a 512KE or later Macintosh, and requires 1MB of RAM.

ComputerEyes is a hardware and software system that digitizes images from any standard video source (video camera, VCR, videodisc, and others). Under software control, the system scans the video signal and captures images into the graphics memory of the computer. It then displays images on the screen, and allows modification with several image-manipulation options. Images are saved to disk for use with other graphics programs.

The ComputerEyes system software supports the graphics capabilities of all Macintosh computers. On a Macintosh II, images display with 256 grays for a near-photographic image. On other Macintosh systems, images display with several options of dither patterns to maximize image quality for all types of images.

Captured images may be saved to disk in a number of formats independent of the computer's display capabilities. Formats supported by ComputerEyes include MacPaint, PICT, gray-scale, and bit-mapped TIFF and Encapsulated PostScript.

With these file formats, ComputerEyes images can be imported to graphics programs, desktop publishing programs, image databases, drawing or painting programs, authoring systems, and animation programs for image display or printing.

Contact Information

You can find the addresses and phone numbers for Digital Vision and Koala Technologies in separate articles in the Tech Info Library.

CP/M: Cursor addressing

Below is a table for the Cursor commands required when using CP/M 2.21 on the Apple III.
This article has been archived and is no longer updated by Apple.
Note: All of the commands are offset by 128 decimal. This prevents CP/M BDOS from interpreting control codes (Tab for example) in the cursor command sequences.

Command	AIII Dec	AIII Hex	CP/M Dec	CP/M Hex
Turn Screen ON	15	0F	143	8F
Turn Screen OFF	14	0E	142	8E
Normal Video (White on Black)	17	11	45	91
Inverse Video (Black on White)	18	12	146	92
Lead-in, Cursor Addressing	26	A	154	9A
Horizontal (X-Axis) Offset	0	0	128	80
Vertical (Y-Axis) Offset	0	0	128	80
Clear Screen (& Home Cursor)	28	1C	156	9C
Clear to End of Screen (From Cursor)	29	1D	157	9D
Clear to End of Line (From Cursor)	31	1E	159	9E
Clear line	30	1E	158	9E
Setup - Initialize Screen to 80x24	16 03	10 03	144 03	90 03
Home Cursor (Do Not Clear)	2	0C	140	8C

Note: The Setup command; this places the console in 80x24 text format if it is not already there.

For additional information on the subject, refer to the Standard Device Drivers Manual supplied with the Apple III.

AppleTalk Internet Router: How To Install with System 7

How do I install Internet Router 2.0 on a Macintosh running System 7?
This article has been archived and is no longer updated by Apple.
Important Note: Internet Router 2.0 is not compatible with System Software 7.1. Computers running System Software 7.1 require the Apple Internet Router 3.0 Basic Connectivity Package.

If you are running a system software version prior to 7.1, then there are two ways to correctly install the AppleTalk Internet Router (AIR) 2.0 Macintosh running System 7.

The best and easiest way to install the AIR 2.0 on a System 7 Macintosh is to use the latest Network Software Installer (NSI) disk. To do this, run the Installer and select the "Customize" option. Select the "AppleTalk Router (v 2.0) for System 7" option and install. The installer will ask for the AIR 2.0 disk and properly install the software.

The second method is to manually install the files from the AIR 2.0 disk. Here is the installation procedure as found on page 100 of the "System 7 Group Upgrade Guide":

Step One

Install System 7 along with EtherTalk or TokenTalk.

Step Two

Insert the AppleTalk Internet Router 2.0 disk.

Step Three

Open the System file on the router disk. The System window lists desk accessories and fonts.

Step Four

Drag the Router desk accessory to the System Folder icon on your System 7 hard disk. A dialog asks "Put this desk accessory into the Apple Menu Items folder?"

Step Five

Click OK.

Step Six

Close the System window.

Step Seven

From the AppleTalk Internet Router 2.0 disk's System Folder, drag the following files to your System Folder:

- LocalTalk (Modem)
- LocalTalk (Built-in)
- Router

A dialog asks, "Put these items into the places they belong?"

Step Eight

Click OK.

Step Nine

Restart your Macintosh computer.

EtherTalk NB Card: System 7 and Compatibility Issues

Is the EtherTalk NB Card, Rev K, required for System 7 users or does it not matter?

This article has been archived and is no longer updated by Apple.
System 7 does not pose any compatibility issues for EtherTalk cards. Here is a list of the Apple EtherTalk NB and Ethernet NB Cards that are compatible with the various Macintosh II class systems:

* Macintosh II or Macintosh IIx:

EtherTalk NB Card (M0410LL/A), Rev. J, K, L, or M
Ethernet NB Card (M0417LL/A)

* Macintosh IIcx, Macintosh IIsi, or Macintosh IIci:

EtherTalk NB Card (M0410LL/A), Rev. K, L, or M
(Rev L or M on Macintosh IIci with on-board video)
Ethernet NB Card (M0417LL/A)

* Macintosh IIfx:

EtherTalk NB Card (M0410LL/A), Rev. K, L, or M (Rev J WON"T work)
Ethernet NB Card (M0417LL/A)

Note: There is a remaining bug that affects Macintosh IIci owners who use the EtherTalk revision K card. Ethernet performance is adversely affected when a user starts up the Macintosh IIci in 2-bit (4 colors) or more, using on-board video. To workaround this problem, the user can use a revision L or M card, or not use on-board video (i.e. use a video card), or use only black-and-white video.

AppleShare PC: How to Run Microsoft Mail on a UngermannBass LAN

What is the most reliable setup for running and printing Microsoft Mail over AppleTalk from an IBM that is also on a UngermannBass LAN?

This article has been archived and is no longer updated by Apple.
Here's what we suggest for a setup:

NOTE: There are two lines below that have a character known as the "at symbol", which is above the number 2 on most standard keyboards. When you see "<at symbol>" listed in the code below, you type in the actual symbol, not the string "<at symbol>." AppleLink does not allow use of that character in an article.

* PS/2 80
* 4MB RAM
* DOS 3.3, Windows 3.0
* an UngermannBass Card
* DayStar AppleTalk card
* AppleShare PC 2.01 software
* Microsoft Mail for DOS software.

Here's what happens when under Windows (with the UngermannBass network drivers and Windows already loaded):

1) Program Manager calls Mail.PIF

2) Mail.PIF calls MSMAIL.BAT

3) MSMAIL.BAT loads AppleShare PC software

4) MSMAIL.BAT starts Microsoft Mail for PC.

5) When exiting Microsoft Mail, MSMAIL.BAT unloads the AppleShare PC drivers.

A key thing you'll need to duplicate this setup is the MSMAIL.BAT file. Here it is:

```
echo off
D:\\ASPC\\LSL > nul
if errorlevel 1 goto aspc_err
D:\\ASPC\\DSTARLT /NAME=DSTARLT > nul
if errorlevel 1 goto aspc_err
D:\\ASPC\\ATALK > nul
if errorlevel 1 goto aspc_err
D:\\ASPC\\PAP_WS > nul
if errorlevel 1 goto aspc_err
d:\\aspc\\compat > nul
REM *** Memory usage for the above programs is approximately 75K bytes.
goto skip_aspc
:aspc_err
echo *** A fatal error has occurred while loading AppleShare PC. ***
pause *ASPC*
:skip_aspc
d:
cd\\msmail2
mail
d:\\aspc\\anet remove all
```

Here are some autoexec.bat, config.sys, and Mail.PIF files:

config.sys
device=C:\\himem.sys
device=C:\\dasddrvr.sys
shell=c:\\command.com /P /E:768

A/UX: No Support for AT&T‘s Remote File System (RFS)

Any way to support RFS (AT&T's Remote File System) from Mac OS or A/UX?
This article has been archived and is no longer updated by Apple.
Neither the versions of A/UX are based on SYS V.2.2 (5.2.2) nor Mac OS support RFS.
Published Date: Feb 18, 2012

VideoSync: How To Use with System 7

VideoSync hangs under System 7 when I launch Monitors Control Panel and select "Options" button (with or without Option key down). When I remove VideoSync things seem to work fine.
This article has been archived and is no longer updated by Apple.
VideoSync is an extension of the Monitors Control Panel. VideoSync needs to be in the same folder as the Monitors Control Panel for the VideoSync controls to show in the Options section of the Monitors Control Panel.

VideoSync stores information in its resource fork. VideoSync expects itself to be at the root level of the System Folder.

For VideoSync to work properly, it needs to be in the same folder as the Monitors Control Panel and be at the root level of the System Folder. With System 6, this isn't a problem, in fact it is the only way it will work. With System 7, you need to be a little more creative. The Monitors Control Panel doesn't resolve aliases, so an alias for VideoSync in the Control Panels folder doesn't work.

One solution is to put a copy of VideoSync in the Control Panels folder and at the root level of the System Folder. This isn't good since the VideoSync INIT is loaded twice at startup.

The best solution is to put VideoSync and the Monitors Control Panel at the root level of the System Folder and put an alias of the Monitors Control Panel in the Control Panels folder (for convenience). Then restart your Macintosh.

Those using the 8*24 GC software will have to remove it.

For information on the VideoSyncII extension please see TIL article number 26110: VideoSyncII

ImageWriter Manual Errata: Producing slashed & unslashed zeroes

This article has been archived and is no longer updated by Apple.

Page 42 of the Imagewriter User's Manual, Part 1, has reversed the commands for producing slashed and unslashed zeros. The correct commands are:

Code Decimal Hex Effect

ESC-Z 27 90 $1B $5A Unslashed
CTRL-@ CTRL-A 0 1 $00 $01

To print unslashed zeros, send: CHR$(27);CHR$(90);CHR$(0);CHR$(1).

ESCAPE D 27 68 $1B $44 Slashed
CTRL-@ CTRL-A 0 1 $00 $01

To print slashed zeros, send: CHR$(27);CHR$(68);CHR$(0);CHR$(1).

Once the Imagewriter has received your instructions, it will continue to follow them until the printer is turned off. Therefore, you may use a word processor or other application program to print slashed or unslashed zeros after setting up the Imagewriter appropriately.

If Applesoft sends codes directly to the printer, zeros may be printed as you desire, but other side effects, such as double line spacing, may occur.

The sample program below sends the appropriate codes to the Imagewriter through a small machine language routine. This bypasses Applesoft's setting the high bit which may cause the Imagewriter to interpret information incorrectly.

```
10 POKE 768,169 : POKE 769,0 : POKE 770,32 : POKE 771,237 : POKE
772,253 : POKE 773,96
20 D$ = CHR$(4)
30 PRINT D$;"PR#1"
40 PRINT "LINE ONE - 0000 - NO SLASHES"
50 REM SEND CODES TO SLASH ZEROS
60 PRINT CHR$(27);"D"; : POKE 769,0 : CALL 768 : POKE 769,1 : CALL 768
70 PRINT "LINE TWO - 0000 - SLASHES"
80 REM SEND CODES TO UNSLASH ZEROS
90 PRINT CHR$(27);"Z"; : POKE 769,0 : CALL 768 : POKE 769,1 : CALL 768
100 PRINT "LINE THREE - 0000 - NO SLASHES"
110 PRINT D$;"PR#0"
120 END
```

Desktop Macintosh Computers: How Much Mass (Weight) Can They Support?

I would like to know how much mass (weight) I can place on top of my Macintosh. How heavy a monitor can the cases of desktop Macintosh computers support?

This article has been archived and is no longer updated by Apple.

Two issues usually dictate what you put on top of the computer: stability and ergonomics. For instance a tall, heavy monitor placed on a computer with a small footprint, such as a Macintosh IIci or Macintosh LC, would be less stable than the same monitor placed on a Macintosh II. Also, if the monitor is perched too high relative to the angle of sight, the issue of ergonomics may become a factor. The best approach is to experiment with different placements of a computer and monitor.

Macintosh Model	Max Supportable Mass	
	kg	pounds
Macintosh 630 Series	22.7	50.0
Macintosh Duo Dock	22.7	50.0
Macintosh Duo Dock II	38.6	85.0
Macintosh Duo Dock Plus	38.6	85.0
Macintosh II/IIx/IIfx	25.0	55.0
Macintosh IIcx/IIci	15.9	35.0
Macintosh IIsi	15.9	35.0
Macintosh IIvx/IIvi	22.7	50.0
Macintosh LC, LC II, LC III	22.7	50.0
Macintosh LC 475	15.9	35.0
Macintosh Performa 400 through 430	22.7	50.0
Macintosh Performa 450 through 476	15.9	35.0
Macintosh Performa 600/600CD	22.7	50.0
Macintosh Performa 630 Series	22.7	50.0
Macintosh Performa 6100 Series	22.7	50.0
Macintosh Performa 6200/6300 Series	22.7	50.0
Macintosh Quadra 605	15.9	35.0
Macintosh Quadra 610	22.7	50.0
Macintosh Quadra 650	22.7	50.0
Macintosh Quadra 660AV	22.7	50.0
Macintosh Quadra 700	15.9	35.0
Power Macintosh 4400	22.7	50.0
Power Macintosh 6100	22.7	50.0
Power Macintosh 7100	22.7	50.0
Power Macintosh 7200	31.8	70.0
Power Macintosh 7300	31.8	70.0
Power Macintosh 7500	31.8	70.0
Power Macintosh 7600	31.8	70.0
Power Macintosh G3 Desktop	31.8	70.0

NOTE: Tower and minitower computers--such as the Power Macintosh 9600, 8600, G3 Minitower and Performa 6400 and 6500 series computers--are not designed to support a monitor.

A/UX 2.0 and 2.0.1: "f77 open()" Problem Workaround

The f77 open() BUG is a long-standing problem in the f77 I/O runtime library (libI77.a), and I have seen this problem in other f77 implementations based on UNIX System V. The reason this problem hasn't been fixed is because it doesn't show up in the Fortran Compiler Validation Suite, the principle test suite for f77.

This article has been archived and is no longer updated by Apple.

Here are two files, named err.o and open.o, you can use while waiting for a version of A/UX that doesn't have this problem. You can either include these files when linking f77 programs, or these files can replace the f77 I/O runtime library files. (Replacing the files makes them a permanent part of the f77 system.)

To include the files in an f77 link, simply add their names to the list of files being linked together by the f77 command. For example:

```
f77 -o test test.f err.o open.o
```

To replace these files into the f77 I/O runtime library, enter the following command (you must be super-user to do this):

```
ar rv /usr/lib/libI77.a err.o open.o
```

Once you replace the files in the library, any f77 programs you link will be fixed automatically.

This has been fixed in A/UX 3.0.

A/UX: 14-Character Filename Limit in SVFS

The filenames on my A/UX partition are limited to 14 characters. If the filename has more than 14 characters it is truncated to just 14.

How can I change this, so that the system lets me use a filename with more than 14 characters?
This article has been archived and is no longer updated by Apple.
In A/UX, there is a 14-character limit in a filename in any SVFS (System V File System) partition. These files must be in an A/UX SVFS partition. However, UFS (Berkeley Fast File System) does not have this limit; it can be up to 255 characters long.

Copy your files to an UFS file system and rename them with a longer filename. Or, convert a SVFS into an UFS by following these steps:

1. Back up all SVFS files.
2. Create a new UFS partition.
3. Copy the files to the new UFS partition.
4. Rename the files to longer filenames in the UFS partition.

A/UX 2.0.1: Correction to CD-ROM Installation Instructions

I've just received the complete A/UX 2.0.1 package and I've found some minors problems installing it.

Just as I did with A/UX 2.0, here's what I'm doing:

1) Initialize and partition the disk with Apple HD Setup.

2) Install Macintosh System 6.0.7 on the Macintosh partition.

3) Copy the contents of the disks "A/UX Startup" and "A/UX Startup Utilities" onto the Macintosh partition.

4) Launch A/UX Install from the disk "Floppy Launch".

5) Insert the disk "Floppy Root" at prompt.

6) Answer the questions and then reboot.

7) Launch the application "Read disk".

8) At this point I can't find the disk "Kernel Archive". The shipping list doesn't mention this disk. Then, I searched in the installation documentation (which is an A/UX 2.0 version and it indicates that I have to launch "Read disk".

9) Finally, I launch A/UX Startup and the installation is complete.

So, my questions are:

*⏄What is "Read disk" for, since I don't need this application to install A/UX 2.0.1?

* Why doesn't the documentation contain an addendum to indicate the change in the installation procedure?

This article has been archived and is no longer updated by Apple.

There is problem when installing a complete A/UX 2.0.1 from CD-ROM by following the installation instructions in the A/UX 2.0 Installation Guide.

When installing a complete A/UX 2.0.1 from a CD-ROM, ignore steps 17 through 20, and double-click A/UX Startup instead. The "Kernel Archive" disk is not included in A/UX 2.0.1, and the "read disk" is no longer needed for installing A/UX 2.0.1

A/UX 2.0 and 2.0.1: adduser Problem

Is there a bug in /etc/adduser, specifically in /usr/lib/addusersub A/UX 2.0?

This article has been archived and is no longer updated by Apple.

Yes there is a problem with the adduser in both A/UX 2.0 and A/UX 2.0.1.

When adding users in interactive mode the first available UID>=1000 is used. But if an entry in the /etc/passwd has a UID>=1000 and the password field is empty (for example, tom::1007:50:Tom van Peer,ois,,:/users/tom:/bin/ksh), this UID is used for the new user.

This has been fixed in A/UX 3.0.

Unix Shell Scripts for Remote Printing

Do you have any information regarding Unix shell scripts for printing from SystemV to SystemV or from SystemV to BSD and vice versa?

This article has been archived and is no longer updated by Apple.

Thank's to Gilles Allain for sending us UNIX scripts that print from SystemV to SystemV or from SystemV to BSD and vice versa. These scripts have been written by Alsys (ADA from A/UX) which is allowing us to freely distribute them.

```

MacX 1.1: Command-B Copy Problem

I'm using MacX 1.1 with an HP 9000 via MacTCP. Using a Macintosh IIci, Macintosh IIcx, and Macintosh IIx, here is the setup:

* System 6.0.5
* MacX application, memory size 5000K
* 8MB RAM

When I do a Command-B copy in MacX to the clipboard, the graphic pastes to the clipboard only for the Macintosh IIci--the Macintosh IIcx and the Macintosh IIx produce a white box in the clipboard.

Any ideas on what may be causing this problem? Is the processing speed of the Macintosh IIcx and the Macintosh IIx too slow on the network to handle the copy? I'm not copying a large or complex graphic from the HP 9000.

This article has been archived and is no longer updated by Apple.
We haven't seen this problem before. We have a Macintosh IIcx running Macintosh OS 6.0.7 and MacX 1.1. For us, Command-B for copying selected area works properly. We don't see any processing speed slowdowns on Command-B Copy on our Macintosh IIcx either. There is, however, a release note on MacX 1.1 that states:

MacX requires the presence of 32-bit QuickDraw to support one feature: the conversion of color PICTs to X11 selections. If you do install 32-bit QuickDraw on your machine (or have a machine at least as new as a Macintosh IIci), you will have this capability--MacX will offer to convert clipboard contents to color PIXMAP and COLORMAP style. If MacX can't find the 32-bit QuickDraw features, MacX will only offer to convert to BITMAP.

Note that 32-bit QuickDraw also adds some performance enhancement and bug fixes on machines older than Macintosh IIci. Also note that 32-bit QuickDraw is built into System 7.0 and later for all machines that support Color QuickDraw.

Is 32-bit QuickDraw installed on your Macintosh IIcx or Macintosh IIx?

Since Command-B was not described very clearly, here are steps to follow:

1) In MacX, do "Command-B" or select "Copy Screen to Clipboard" from the Window menu. The mouse pointer becomes '+' sign.

2) Select whatever area of screen you want. The selected area (graph or text) will be copied to the Clipboard.

A/UX: Missing Toolbox ROM Routines (9/94)

Using A/UX 3.0, I can't compile my programs because four routines aren't found by the linker.

Here's a sample program that demonstrates missing routines:

----------ttt.c----------

```
#include <printing.h>
#include <osutils.h>

main()
{
int rom,machine;

GetDateTime();
Environs (&rom, &machine);
PrStlInit();
PrDlgMain();
}
```

----------Makefile----------

```
# makefile for testing ttt.c

CFLAGS = -O -I /usr/include/mac -B /usr/lib/big/
LDFLAGS = /usr/lib/low.o -lmac_s -lat -lld -lmr -lc_s /lib/crtn.o \\
/usr/lib/low.ld

SRC = ttt.o

ttt: $(SRC)
ld /usr/lib/maccrt0.o /lib/crt2.o -o ttt $(SRC) \\
$(LDFLAGS)
```

----------StdOut/StdErr----------

```
$ make
cc -O -I /usr/include/mac -B /usr/lib/big/ -c ttt.c
ld /usr/lib/maccrt0.o /lib/crt2.o -o ttt ttt.o \\
/usr/lib/low.o -lmac_s -lat -lld -lmr -lc_s /lib/crtn.o
/usr/lib/low.ld
undefined first referenced
symbol in file
GetDateTime ttt.o
Environs ttt.o
PrStlInit ttt.o
PrDlgMain ttt.o
ld fatal: Symbol referencing errors. No output written to ttt
Make: *** Error: Update of ttt terminated with exit code 13
Make: [line 10 in /home/dumais/Makefile]
```

I've found alternate ways of getting the time and the machine type, but I can't find a solution for the printing routines.

Where are these routines implemented in A/UX? I have searched the /usr/lib/libmac.a and /usr/lib/libmac_s.a libraries for the missing routines.

This article has been archived and is no longer updated by Apple.
In A/UX 2.0, 2.0.1, and 3.0 we have verified this problem. The above A/UX Toolbox ROM routines are not included in any of the Macintosh libraries and aren't supported by A/UX.

Apple Writer IIe: Using "Connect Keyboard to Printer" w/the SSC

This article describes how to use the "Connect Keyboard to Printer" option in Apple Writer IIe.
This article has been archived and is no longer updated by Apple.
If you plan to use the "Connect Keyboard to Printer" option in Apple Writer IIe with the Super Serial Card, be sure to refer first to page 138 of the manual ("Connecting the Keyboard to the Printer").

Take note especially of the warning about the Super Serial Card and of the fact that you must type CTRL-I T SPACE E RETURN in order to avoid the occurance of unwanted tabs in your printed text.

Macintosh: Printing From Mac OS Through A/UX Spooler

Can I use an A/UX spooler (Berkeley or System V) to spool AppleTalk printing? For instance, if I am running under the Mac OS and want to print to a LaserWriter, can I access a spooler on A/UX (as A/UX can do for other UNIX systems)?
This article has been archived and is no longer updated by Apple.
The Columbia AppleTalk Package for UNIX (CAP) from Columbia University does what you want. The CAP package includes CAP libraries and utility programs such as:

look: finds and reports AppleTalk entities on the network.

looks: finds "LaserWriters" on the network and returns their status.

papif: spools jobs from UNIX to a LaserWriter over AppleTalk

lsrv/lwsrv/iwsrv: receives jobs from Macintosh by pretending to be a LaserWriter or AppleTalk ImageWriter.

AUFS: stands for AppleTalk Filing Protocol UNIX File Server. It is the server implementation of AFP running on UNIX corresponding to Apple's AppleShare server for the Macintosh. AUFS is not AppleShare, however. AUFS requires that the AppleShare workstation software be installed on the client Macintosh.

For more information about CAP and Kinetic Internet Protocol (KIP), including where to get them, see the following Tech Info Library article:

Article 3142: "**UNIX: KIP And CAP Information**"

A/UX 2.0.1: No Toolbox Change from A/UX 2.0

I need a list of all Macintosh OS managers not supported under A/UX 2.0.1.

This article has been archived and is no longer updated by Apple.

```
According to A/UX Engineering, there are NO changes in the support of A/UX
Toolbox from A/UX 2.0 to 2.0.1.  Therefore, the ROM library support
information in "A/UX 2.0 Toolbox: Macintosh ROM Interface" documentation is
still accurate.

The following are ROM libraries NOT supported by A/UX 2.0 Toolbox:
* Apple Desktop Bus
* Deferred Task Manager
* SCSI Manager

The following are PARTIALLY supported by A/UX 2.0:
* AppleTalk Manager
* Event Manager, Operating System
* File Manager
* Gestalt facility
* Script Manager
* Segment Loader
* Serial Driver
* Slot Manager
* Sound Manager
* Utility, Operating System
* Vertical Retrace Manager

The following are supported, but the FUNCTIONALITY is not identical:
* Event Manager, Toolbox
* Floating-Point Arithmetic and Transcendental Functions Packages
* Shutdown Manager
* System Error Handler
* Time Manager

For more detailed information, refer to Chapter 5 of Inside A/UX Macintosh
in A/UX Toolbox: Macintosh ROM Interface documentation.
```

Published Date: Feb 18, 2012

A/UX: TextEditor Issue

I just found a new small bug in A/UX. This bug appears when using TextEditor with an extended keyboard. If you hit the HELP key, an alert appears on the screen. In this alert you can read:

Unable to open the help file "MPW.Help".
#OS error -43 (Error message file not available)

This article has been archived and is no longer updated by Apple.
The behavior you describe has been verified. It is a TextEditor bug on both A/UX 2.0 and 3.0.
Published Date: Feb 18, 2012

A/UX 2.0 "kohrnerstone" Benchmark?

Are there any benchmarks for a Macintosh IIfx with A/UX 2.0.X running the Kohrnerstone or similar benchmarks that take into account I/O speed?

This article has been archived and is no longer updated by Apple.

Here are the results of benchmarks compiled with the standard compilers (C, Fortran) included in the A/UX package.

	Macintosh IIci	Macintosh IIcx	Macintosh IIfx	
mips	3,02	2,00	5,30	(Joy Mips)
dhrynr	3332,00	2105,00	5630,00	(dhrystone no register)
dhryr	3545,00	2228,00	5828,00	(dhrystone register)
dhrynro	5529,00	3494,00	10270,00	(no register with -o option)
dhryro	5571,00	3507,00	10101,00	(register with -o option)
Kwhets	928,00	595,00	1347,00	(whetstone single precision)
Kwhetd	858,00	540,00	1381,00	(whetstone double precision)
linpackrsKflops	164,00	103,00	264,00	(linpackrs, single precision,with optimisation,rolled):264 Kflops)
linpackusKflops	173,00	110,00	284,00	(linpackus, single precision,with optimisation,unroll):264 Kflops)
linpackrdKflops	152,00	95,00	246,00	(linpackrd, double precision,with optimisation,rolled):264 Kflops)

A/UX: Manual Pages of launch(1) are Wrong

I am using launch to start Macintosh Applications from a motif menu in a rooted MacX, mwm window. I am having difficulty with this due to differences between the manual pages and the /mac/bin/launch executable. Specifically, under both A/UX 2.0 and 2.0.1, the manual page for launch[1] gives the options of:

```
launch -p[it] filename document...
```

Commando gives the same options. The usage provided by the command is:

usage: `launch [-padr] appName [docName ...]`

Is this a bug?
This article has been archived and is no longer updated by Apple.
There is a conflict with the usage of launch(1) between the manual page and the launch program itself. The usage of manual pages of launch(1) are wrong. This is resolved in A/UX 3.0
Published Date: Feb 18, 2012

A/UX: Powerfail Feature Not Supported

I want to use the powerfail calls in A/UX 2.0. I want to use the /etc/powerfail script to clean up when someone pulls the plug on a computer (or hits the reset programmer's switch).

Can the /etc/powerfail script be used this way? Will the system have enough time to execute these commands?
This article has been archived and is no longer updated by Apple.
The /etc/powerfail does not work under A/UX because the Macintosh hardware does not have enough backup battery power.
Published Date: Feb 18, 2012

Apple II 5.25 Drive: Using It With Other Disk Controller Cards

This article has been archived and is no longer updated by Apple.

New Apple II 5.25 drives can be connected to controller cards other than the ones specifically designed for those drives.

- an Apple 5.25 drive can be daisy-chained to a UniDisk, either 5.25 or 3.5.

- an Apple 5.25 drive can be connected to a DuoDisk controller card.

- an Apple 5.25 drive can be connected to a Disk II controller card, if you first use Quark's adaptor to make the Apple 5.25 drive's cable fit the Disk II controller card.

Sony GDM-1901-12 Monitor: Incompatible with Macintosh

Can I connect a Sony GDM-1901 (from Masscom) monitor to my Macintosh?

This article has been archived and is no longer updated by Apple.

Sony's tech support has stated that no version of the GDM-1901 will work on any Macintosh.

The GDM-1901 was an OEM product from Sony to a variety of vendors. It is now an obsolete product. When these were manufactured each vendor specified their requirements for timing to Sony; thus, each vendor's version of the GDM-1901 is specific to that vendor's computer system. To find out more about a particular vendor's version, contact Sony's monitor tech support at 408-944-4181.

For more information, search under: "Sony"

Macintosh LC: Jumpers are for Apple IIe Card

What are the three jumpers for on the logic board of the Macintosh LC? I believe one is for the Apple IIe card, but I'd like to know what the other two do.

This article has been archived and is no longer updated by Apple.
Installation of a jumper connection on the third set of jumper pins (the ones closest to the "CPE" silk screen marking on the logic board) locks out the Control Panel of the Apple IIe card. The other two sets of jumper pins are reserved by Apple and should never be connected. These jumpers also exist on the Macintosh LC II and Performa 405 logic boards, however the silk screen reads "J17".

When the jumper is installed on the logic board, users will continue to have access to the following Apple IIe Option Panel buttons:

- Quit IIe
- Eject Disk
- Restart IIe
- Return

However, users will not have access to any of the panels used to change Option Panel settings.

Article Change History:
21 June 1994 - Updated to include information on LC II and Performa 405.

System 7: No Need to Install the Communications Toolbox

Do I still need to install the Communications Toolbox with System 7?
This article has been archived and is no longer updated by Apple.
With System 7.0, you no longer need to install the Communications Toolbox. Everything that previously needed to be manually installed into the System under the 6.0.x is now included with System 7.0.

Also, there is no longer a Communications Folder. All tools are placed in the Extensions Folder instead. If you are upgrading from System 6.0.x to System 7.0, move the tools to the Extensions Folder and delete the Communications Folder.

The System 6.0.x version of the Communications Toolbox is 1.0; only minor changes were made for System 7.0, and that version is labeled 1.0.1. As long as you have the latest version of System 7.0 you'll have the latest version of the Communications Toolbox.

Macintosh Portable: Screen Dimming with System 7.0 on Network

Article Change History

07/29/92 - REVIEWED
* For technical accuracy.

I cannot get my Macintosh Portable to dim its screen under System Software 7.0. No matter what the Macintosh Portable Control Panel settings are, the screen never dims. The hard drive does spin down at the appropriate time, however.

This article has been archived and is no longer updated by Apple.
The reason the screen does not dim is because dimming of the screen will disable your AppleTalk connection, so the decision was made for Macintosh Portable computers connected to a LocalTalk network that the screen will not dim even if the "sleep" timers expire.

If you are not connected to a LocalTalk network, make AppleTalk inactive, and the screen will dim as you would normally expect. Of course, based on the above information, if you are connected to a LocalTalk network you do not want the screen to dim.

System 7: Edition Manager Edition Files

I have a question about how edition files are handled. I experienced the following with both Excel and Resolve:

1. Open a spreadsheet.
2. Make some columns of data.
3. Publish them on my local hard disk.
4. Close the spreadsheet, saving changes so the edition file remains.
5. Move the edition file to a different place on the hard disk. When I open, modify, and close the spreadsheet, the edition file is properly updated (just to see that the spreadsheet can follow the edition).
6. Close the spreadsheet, mount a file server, and copy the edition file to the file server, deleting the edition file on my local hard drive after the copy is complete.
7. Open the spreadsheet.

At this point, the application creates a new edition file in the location that the local edition file was last placed, ignoring the edition file on the file server.

Is this behavior application-specific, or is System 7.0 doing this? Am I doing something wrong?
This article has been archived and is no longer updated by Apple.
When an application opens a document, it registers every publisher contained within that document with the Edition Manager. If the Edition Manager cannot find the edition, it creates an empty edition in the last known location, and informs the application that it needs to write to this new file.

Therefore, this is standard behavior enforced by the Edition Manager, and applications using the Edition Manager will most likely conform to this behavior.

For more information, consult "Inside Macintosh", volume VI, pp 4-19.

HD SC Setup: Multiple Macintosh Partitions

Is it possible to use HD SC Setup to partition Apple drives for two different versions of Mac OS? Does Apple support multiple Macintosh operating systems on a partitioned hard disk?
This article has been archived and is no longer updated by Apple.
Yes, you can partition one hard disk into multiple partitions having different versions of Mac OS. However, the HD SC Setup will allow only one of the partitions to be a Mac OS partition. This does not mean that Apple doesn't support multiple Macintosh OS partitions on the same hard disk. Third-party utilities allow multiple Macintosh partitions and we have never heard of difficulties with them.

In most cases the typical Macintosh user will equate the terms volume and hard drive. If a hard drive has been partitioned into multiple Macintosh volumes then it is important to distinguish between the terms. Each partition will look like a volume to the operating system. Apple does not recommend putting more than one System Folder on a volume. If one hard drive contains multiple partitions then there is no reason why each partition couldn't have a System Folder on it. This would be no different than having multiple hard drives attached, each with a System Folder on it.

Third-party products can do this. Be aware that many third-party drive software developers are either revising or have already revised their software for System 7.0 compatibility. Be sure you use a version that the developer explicitly states support for System 7.0 and newer.

HyperCard IIGS: Script for Setting TextColor

What is the HyperCard IIGS script to highlight text on a card field to a certain color?

This article has been archived and is no longer updated by Apple.
Field properties (as listed and documented in the HyperTalk Beginners Guide) include frameColor and textColor. FrameColor cannot be changed using a script.

TextColor can be changed to one of the sixteen current colors in the colorSet. Here is the script:

set the textColor of card field field1 to n

where n is a number from 1 to 16. The highlight color is always black; the text within the highlight becomes the compliment of the textColor.

Note: Be careful about being misled by the actions of the "color" section of the "field info" dialog where the highlight color is the same as the textColor and the text within the highlight becomes white.

Works-to-Works 2.0: Available From Microsoft

I am trying to use Apple File Exchange (AFE) and the Microsoft Works-to-Works Transporter to convert Appleworks 3.0 data to Macintosh Microsoft Works via AppleShare. AFE only recognizes the Appleworks data as ProDOS files on a ProDOS floppy disk. AFE treats these files as Macintosh data when it appears on the file server.

Is there a way to bring up the ProDOS-to-Mac menu under AFE?

This article has been archived and is no longer updated by Apple.
Works-to-Works Transporter 2.0 will convert Appleworks 3.0 files to Microsoft Works files. You can get a copy of the utility from Microsoft by calling them and requesting Works-to-Works Transporter 2.0.

For more information, search on "Microsoft".

DaynaFile: Use Driver Version 2.8 with Macintosh IIfx

I connected a DaynaFile floppy drive to the Macintosh IIfx. Everytime I insert a disk into the drive, the drive reads it and then the system locks up.

Any ideas?

This article has been archived and is no longer updated by Apple.

Dayna's Tech Support group told us that version 2.8 of the driver is required to use the DaynaFile on the Macintosh IIfx. Customers can get a copy of the driver by contacting Dayna directly.

For more information, search under: "Dayna"

Apple III: NPL III

This article has been archived and is no longer updated by Apple.
When you direct reports from NPL III to a DMP connected via device-name .DMP and NPL seems to refuse this name after the C>DISK:, you must revise the driver file of CONSOLE:, SILENTYPE:, PRINTER:, and DISK:.

NPL III is written in Pascal. Pascal scans the drives when it boots and assigns unit numbers depending on the type and order in which they are loaded. Assuming you are using the diskettes, delete the .PRINTER driver from the driver file and add your .DMP driver. Rename .DMP to .PRINTER.

If you are using Catalyst, you'll have to arrange the drivers so that the Pascal Filer's 'Volumes' command shows .DMP as Unit #6.

StyleWriter: Use Of Power Converter Suggested Overseas

Is a power adapter or transformer necessary to use the StyleWriter in Europe and the Soviet Union? This is to convert 110/60 to 220/50.

This article has been archived and is no longer updated by Apple.
While it is possible to run the StyleWriter on 220V/50Hz with the aid of a power converter (see the AppleLink Tech Info Article "Using Apple Equipment Overseas"), the cleanest solution would be to purchase an Apple AC Adapter (transformer) appropriate to the local power conditions.

Transformers of all kinds can be ordered by any Authorized Service Provider. The current service price list shows transformers available for the following areas:

USA 699-2050
Japan J699-2050
UK B699-2050
Australia X699-2050
Europe Z699-2050

If you don't have time for a local service provider to order the transformer, it can be purchased from an Apple dealer at your destination.

LaserWriter: How To Determine PostScript Version, ROM Revision

Is there a way to determine the version of the PostScript driver on an Apple LaserWriter? Is there a way to determine the disk driver version on the Hard Drive? Is special software is used to determine either of the above?
This article has been archived and is no longer updated by Apple.
To determine the PostScript version and ROM revision levels on a LaserWriter, use the code below in a PostScript dump utility.

Caution: If you choose to use the PostScript code provided in this article, you assume all risks involved in making these changes. PostScript code, if not entered correctly, can place a laser printer into a condition requiring service.

```
%=========================================================
% Begin PostScript Code
%
serverdict begin 0 exitserver
/Helvetica findfont
15 scalefont
setfont
/str 40 string def
72 700 moveto
(LaserWriter Name:  ) show
statusdict begin str printername show
72 675 moveto
(PostScript version:  ) show
statusdict begin version show
72 650 moveto
(ROM revision level:  ) show
statusdict begin revision str cvs show
showpage
%
% End PostScript Code
%=========================================================
```

The output will look something like:

```
LaserWriter Name: xxxxxxxx
PostScript version: xx.x
ROM revision level: x
```

Determining the version of a disk driver is different for each manufacturer. As far as we know, there is no package that will return the information on any drive.

Personal LaserWriter LS: Total Effective RAM

I understand that with the standard 256K RAM, the Personal LaserWriter LS will effectively appear to have 1.5MB. With the addition of the 1MB upgrade, does one get an effective 2.5MB RAM?

This article has been archived and is no longer updated by Apple.
The compression/decompression scheme allows the Personal LaserWriter LS to image documents that would not normally fit in 512K of RAM. The amount of compression depends on the image, and is not really predictable. Apple's testing showed that the only pages that could not fit in the standard RAM (U.S. Letter paper) were graphics containing patterns that don't lend themselves to effective compression. It was somewhat easier to overflow RAM when printing on legal sized paper.

With the additional RAM installed (making the total 1MB), Testing was unable to find a document that the printer would not image.

LaserWriter Driver: Missing BoundingBox Parameters

Why doesn't Apple software put values in the PostScript EPS file for the BoundingBox parameter? How can I get values inserted there if they cannot be generated? I need this information for output to DEC PostScript printers.

Sample output:

```
%=========================================================
% Begin PostScript Code
%
%!PS-Adobe-2.0
%%Title: Clone of Contacts
%%Creator: PrintMonitor
%%CreationDate: Wednesday, May 8, 1991
%%Pages: (atend)
%%BoundingBox: ? ? ? ?
%%PageBoundingBox: 30 31 582 761
%
% End PostScript Code
%=========================================================
```

Caution: If you choose to use the PostScript code provided in this article, you assume all risks involved in making these changes. PostScript code, if not entered correctly, can place the LaserWriter into a condition requiring service.
This article has been archived and is no longer updated by Apple.

The %%BoundingBox comment is a PostScript document structuring convention (DSC) used mainly for Encapsulated PostScript Files (EPSF). Its primary purpose is to inform an application importing the EPSF of the actual page mark boundaries. This allows the application to properly prepare for, and clip, the imported image.
BoundingBox coordinates are determined by computing the smallest rectangle that would enclose the sum of all pages in a job. This rectangle's coordinates are based on PostScript's default user space: origin at the lower left, with X increasing to the right and Y increasing to the top.

As an example, consider a two-page document. Given the following enclosing coordinates of page 1 and 2, the BoundingBox is the rectangle that completely encloses the sum of both pages:

	Lower Left		Upper Right	
	X	Y	X	Y
Page 1	95	102	500	700
Page 2	120	225	557	600
	---	---	---	---
BoundingBox	95	102	557	700

The LaserWriter driver doesn't include the BoundingBox coordinates because it doesn't know what they would be at the time the BoundingBox comment must be generated We would have to run through the entire print job once to compute the BoundingBox, and then a second time to actually print the document. That would be very slow. What you see instead is that BoundingBox is sent with its question mark arguments, but PageBoundingBox is computed for the first page and sent with the job. Since PageBoundingBox only applies to a single page, its values can be computed for the first page as it is generated. It has little real value in the context of a large (multi-page) document, but it is still included, mainly for historical reasons. We've supplied it since the early versions of the LaserWriter driver.

The only way to create usable BoundingBox numbers would be to supply those that enclose the largest possible rectangle. This would ensure that nothing is ever clipped by the receiving program. The outside borders of any page can be defined by the following BoundingBox:

Lower Left		Upper Right	
X	Y	X	Y
0	0	612	792

Therefore, supplying these numbers as the BoundingBox would be valid for any printable page or job. Unfortunately there is no simple way to substitute these numbers for the question marks currently used. If the print job were dumped to a disk file, it could be edited to include the numbers, but this seems like it would

be very annoying for multiple print jobs.

It seems unlikely that the BoundingBox comment is absolutely required for DEC laser printers, so it would help to know that the information was needed for a spooler or some printer host software. PostScript itself doesn't generally use the BoundingBox comment. As mentioned earlier, it is used so that importing software can know what to expect, and sometimes for spooling software.

It's important to note that our LaserWriter driver performs many PostScript operations that are not compatible with the EPSF format. This is not in any way abnormal for a print driver, but the result of importing a complete LaserWriter job in another document would produce very unpredictable results. The files generated by the LaserWriter driver are not EPSF compliant.

TA46786_MacDFT_Upgrade_for_System_Status_(TIL08335).pdf

MacDFT: Upgrade for System 7 Status

What is the status on the MacDFT upgrade for System 7?

This article has been archived and is no longer updated by Apple.

MacDFT will not be upgraded for System 7. The replacement product, SNA*ps, was announced at the end of June 1991. Search under SNA*ps for more details

Published Date: Feb 18, 2012

Ethernet: Minimum Packet Lengths and Cisco Routers

What is the minimum length of an Ethernet packet? Since AppleTalk frequently uses small packets for NBP, ZIP, and so forth, does it pad packets to this "minimum" length? Are there any known interoperability issues with cisco routers, AppleTalk, and minimum length packets?
This article has been archived and is no longer updated by Apple.
The IEEE 802.3 standard specifies that the minimum length of an Ethernet packet is 60 bytes. If the total length of a packet is less than 60 bytes, pad bytes must be added after the data to bring the packet size up to 60 bytes.

An additional four-byte cyclic-redundancy check (CRC) is appended to the end of the packet and is checked by the receiver to determine whether an error occurred.

Traffic less than 64 bytes in length (60 byte packet plus a four-byte CRC) is considered an error by Cisco routers and is ignored.

Pers. LaserWriter: Problems Caused by Too-Small Margins (12/94)

I want to print legal size documents on a Personal LaserWriter LS. The left and right margins are cutting into the text. The margins are set up at 0.265 left and right.

Is this because of the limited memory? Will a memory upgrade fix this problem?

This article has been archived and is no longer updated by Apple.
The problem you've reported exists in both the Personal LaserWriter LS and Personal LaserWriter SC drivers. A memory upgrade will not address the problem.

According to the Personal LaserWriter specifications, the imageable area left and right margins of 0.25 inch should be the same for both US Letter and US Legal sized documents.

InBox: Using with Macintosh System Software 7.0

Can I use InBox with the file sharing capabilities of Macintosh System 7?
This article has been archived and is no longer updated by Apple.
The following is from Sun Select (formerly Sitka Corporation):

Sun Select Tech Note 1404: InBox and Apple's System 7.0

Sun Select- 5/22/91

InBox and Apple's System 7.0 InBox for Macintosh and InBox Plus for Macintosh provide full messaging, routing and administrative functionality under Apple System 7.0. Follow the instructions below to install and use InBox under System 7.0.

Upgrading an InBox Client from System 6 to System 7.0

1) If InBox is installed as a Desk Accessory, use the Font/DA Mover to remove the InBox DA.

2) Use the Apple Installer to upgrade to System 7.0.

3) If the Apple Installer moved the InBox INIT to the Control Panels Folder, drag it back to the root level of the System Folder.

4) Drag the InBox Preferences file from the Preferences Folder to the root level of the System Folder.

5) If you wish to access InBox from the Apple Menu, drag the InBox application into the Apple Menu Items Folder. Do not install the InBox DA into the Apple Menu Items Folder. The InBox DA should not be used on System 7.0 machines.

Note: The InBox INIT must reside at the root level of the System Folder. You can double-click on it to access the Control Panel settings. If you wish to access it from the Control Panels Folder itself, you can make an Alias for it, and drag the Alias to the Control Panels Folder.

Upgrading an InBox Mail Server Message Center from System 6 to System 7.0

* No special procedures are required. The InBox Server INIT will be moved to the Control Panels Folder.

Upgrading an InBox File Server Message Center from System 6 to System 7.0

* No special procedures are required.

Installing an InBox Client on a Macintosh under System 7.0

* No special procedures are required. If you wish to access InBox from the Apple Menu, make sure you install InBox into the System Folder. Then drag the InBox application into the Apple Menu Items Folder. Do not install the InBox DA into the Apple Menu Items Folder. The InBox DA should not be used on System 7.0 machines.

Note: The InBox INIT must reside at the root level of the System Folder. It can be double-clicked on to access the Control Panel settings. If you wish to access it from the Control Panels Folder itself, you can make an Alias for it, and drag the Alias to the Control Panels Folder.

Installing an InBox Mail Server Message Center on a Macintosh under System 7.0

* After using the InBox Administrator to create a Mail Server Message Center on a machine running System 7.0, you must drag the InBox Server INIT from the root of the System Folder to the Control Panels Folder, in order to access the Server INIT from the Control Panel.

Installing an InBox File Server Message Center on a Macintosh under System 7.0

* Copy the InBox Administrator to the hard drive of the Message Center Macintosh launch it from there. Do not launch the Administrator from a floppy disk when creating a File Server Message Center under System 7.0.

Note: To Create a File Server Message Center over the network under System 7.0 (those wishing to create a File Server Message Center on an AppleShare Server might wish to do this), launch the InBox Administrator from an AppleShare Client Macintosh. When you attempt to open the remote volume in the Administrator, you will get the following message: "That name is already used by a folder." Click OK. The remote volume will still be selected in the list box. Click once inside the text box, enter the name of the Message Center, and click the SAVE button.

The System 7.0 Compatibility Checker: If you run the System 7.0 Compatibility Checker on an InBox Client, the InBox INIT will be placed in a folder called "May Not Work with System 7.0". If you run the System 7.0 Compatibility Checker on an InBox Mail Server Message Center, the InBox Server INIT will be placed in this folder as well.

System 7: Novell‘s Notify Extension is Incompatible

The Notify extension from Novell is incompatible with System 7.x.
This article has been archived and is no longer updated by Apple.
The Notify extension version 2.1 from Novell causes severe performance degradation on Macintosh systems running System 7.x. These performance problems extend beyond network performance slowdowns and include actions as simple as opening your hard drive. You should use the latest release of the Notify INIT which is version 3.0.

Below is an excerpt from the Read Me regarding the release:

> NOTIFY v 3.0
>
> This version of the Notify INIT addresses several issues. It includes the fix for a problem with Notify loading on a System 6.x Macintosh with over 8 MB of RAM. It resolves several performance issues when running System 7. And the frequency at which it polls the Netware server for messages has been decreased, which resolves some performance problems on large networks.

System 7: Features and Benefits

This article describes the features and benefits of System 7, and the upgrade offers available.
This article has been archived and is no longer updated by Apple.
System 7 works on all Macintosh computers from the Macintosh Plus on. System 7 is compatible with most of the more than 4,000 Macintosh applications currently shipping, and has inspired many new products.

Benefits

Customers who upgrade to System 7 will receive the immediate benefits of new features such as TrueType¬ font technology, Virtual Memory, File Sharing, System 7 Finder¿, Multitasking, Balloon Help¬ and 32-Bit Addressing.

TrueType

System 7 offers all Macintosh users high-quality text at any size on any Macintosh screen and on the printed page with TrueType, Apple's outline font technology. TrueType is compatible with most existing applications and bitmap fonts and provides users with smooth type quality on the screen and on any output device such as PostScript¿ and non-PostScript printers, imagesetters, and film recorders.

Finder and Balloon Help

The System 7 Finder, also known as the user's desktop, has been simplified so that customers can quickly locate and use their information. All aspects of the Finder--including fonts, desk accessories, control panels and even the System--can be opened by double-clicking on them. In addition, the new System 7 Finder facilitates system management and set-up: files, folders, and applications can now be added to the Apple Menu; users can have outline views of all files and folders; and fonts, system extensions, and control panels, can easily be installed by dragging them to the System Folder.

System 7 also provides Macintosh users with an interactive System-wide Help system. Apple's Balloon Help is non-modal, allowing users to get help while continuing to work. When customers turn on Balloon Help and point to any object on the screen, a balloon appears that describes the object they are pointing to and how to use it. Macintosh software application developers are also incorporating Balloon Help into new releases of their programs. This feature will enable users to learn applications more quickly by providing an easily accessible reference to more features.

Finder and File Sharing

The new Find capability offers users fast and easy access to their files. The user can select Find, then type a word or phrase, and the system searches the disk for files whose names include the word or phrase. Find also offers more advanced options so users can perform more detailed searches. For example, users can find all files that they worked on today or files that were labeled with a specific color.

File sharing allows any user to share designated items (files, folders, and even whole volumes of information) with any other user over the network, without a dedicated file server. File sharing follows Apple File Protocol (AFP) standards, which means that any System 7 user can share files with any Macintosh System 6 user, and--by using third-party products-- with DOS and Windows users. File Sharing includes a complete security model that lets users provide levels of access and password protection.

Aliases allow all Macintosh users to organize their systems the way they prefer and makes it easier to access information. An alias, usually about 2K in size, of a file, folder, application, or volume (even a file server), acts as a pointer to the original object. With aliases, users can have access to documents, folders, and applications from more than one location. For example, a user may work with a particular word processor each day and would like to have it on the desktop but also organized within an applications folder. With aliases, users can do both without taking up much additional space on the hard disk.

Aliases and file sharing work in combination to provide more capabilities. For example, Macintosh users can carry an "office on a disk" by making an alias of their hard disk, placing it on a floppy disk, and when the user goes to any system on a network (across the hall, downstairs, or anywhere else) the user has access to the hard disk by double-clicking on the alias and typing a password.

Memory and Multitasking: Virtual Memory and 32-Bit Addressing

Multitasking is a standard part of Macintosh System 7, allowing users to work on several tasks concurrently. For example, a user can recalculate a spreadsheet, print a file, sort a database, and upload a file to a network while continuing to work on a word processor document. System 7's Virtual Memory expands the Macintosh's memory through software so that Macintosh users can run more and larger applications. Virtual Memory uses the hard disk as an extension to RAM, providing users with more memory when it's needed. In addition, 32-bit addressing allows users to install and access more than 8MB of RAM. The additional memory users can access will provide additional power for large applications and tasks such as animation, computer-aided design, and scientific visualization.

Publish and Subscribe

In 1984, the Apple Macintosh introduced the concept of "copy and paste," allowing users to share graphics and text among different files within

different applications. With System 7, Apple has taken "copy and paste" one step further with dynamic document links known as "publish and subscribe." Publish and Subscribe enables users to link any two documents--regardless of the application--to automatically update the information. This capability of System 7 even works over a network.

Apple Events

Apple events is the underlying messaging language that applications use for communication with other applications. It provides the foundation for applications to seamlessly work together sharing information and features on the same machine or over a network. Through new applications that support Apple events, users will be able to use features of a variety of applications while working in one application. For example, an accounting package can pass inventory data to a spreadsheet, instruct the spreadsheet to graph the data, and retrieve the graph for display in its own report.

Data Access Manager

The Data Access Manager, which ships as a standard component of System 7, provides Macintosh applications with the underlying technology that enables data access from remote host computers, regardless of the host computer, the connecting networks, or the database software.

Upgrade Path

System 7 offers all existing Macintosh users an upgrade path. Apple's design goals required that System 7 run on all Macintosh computers from the Macintosh Plus, Portable, and Classic on up to the latest, most powerful models. In addition, Apple has developed a suite of tools for customers that make the transition to System 7 as easy as possible.

Before You Install

Apple developed a HyperCard¿ stack called Before You Install, to give users a better understanding of System 7 and system compatibility. Before You Install features two sections of information: What's New in System 7, and Compatibility Checker. What's New in System 7 helps customers find out more about System 7 and explore some of the new features before upgrading. The Compatibility Checker provides customers with an automated tool for checking application, desk accessory, and control panel compatibility before moving to System 7. The Compatibility Checker, available in the United States, includes information on over 650 products. A printed Compatibility Guide is also available.

Network Install

As part of the System 7 Group Upgrade Kit, Apple includes a network-install version of the software. Users will be able to upgrade multiple systems over a network with the Macintosh one-button install. This process will alleviate the network administrator's task of manually upgrading many systems in sequence.

Upgrade Kits

System 7 works with all Macintosh computers--from the Macintosh Plus, Portable, and Classic on up--with 2MB of RAM (though 4MB is recommended) and a hard disk. System 7 is available to users in two versions: the System 7 Personal Upgrade Kit, and the System 7 Group Upgrade Kit.

The Personal Upgrade Kit includes ten floppy disks containing System 7 software, the Before You Install stack, and HyperCard version 2.1. The kit contains 90 days of upgrade phone support, new user manuals, and the System 7 Compatibility Guide.

The Group Upgrade Kit includes everything that is in the Personal Upgrade Kit, plus a System 7 CD-ROM, 180 days of upgrade phone support, site license, and Group Upgrade Guide. The System 7 CD-ROM includes a System 7 configuration that can be installed over a network, an array of utilities, and on-line documentation. The Group Upgrade Guide offers network administrators a resource for upgrading small and large groups of users in varied network environments.

Trademarks

Apple, the Apple logo, Finder, and Macintosh are registered trademarks, and Balloon Help and TrueType are trademarks of Apple Computer, Inc. HyperCard is a registered trademark of Apple Computer, Inc. licensed to Claris Corp. PostScript is a registered trademark of Adobe Systems, Inc.

TA46796_Apple_III_RETURN_and_ENTER_(TIL00835).pdf

Apple III: RETURN and ENTER

This article has been archived and is no longer updated by Apple.
In order to differentiate being the RETURN and ENTER keys on an Apple III, you need to redefine the keyboard layout table to command the console driver to return two bytes with every request for a character. While we cannot obtain a document of the format of the keyboard part of the driver, the diagram on page 165 in conjunction with the diagram on page 135 of the Standard Device Drivers manual shows what information is returned in the two byte mode. The ENTER key will return $0D just like RETURN but the second byte will have bit 7 set.

Beware that after enabling the double byte read from Business BASIC, an invokable module is required for text. Two GET statements won't work.

System 7: File Sharing Activates AppleTalk Automatically

Does AppleTalk need to be active before I start file sharing?
This article has been archived and is no longer updated by Apple.
If you start file sharing when AppleTalk is not active, AppleTalk will be activated automatically.
Published Date: Feb 18, 2012

System 7: Creating Groups for File Sharing

How do I create Groups for file sharing?
This article has been archived and is no longer updated by Apple.
Whenever more than one user needs access to a particular folder on your system, you can create a group. The group contains the names of all the users who belong to it. Each user can be a member of as many groups as desired. Once the group is created, access permission can be controlled at the group level.

After creating all the individual users, create a group to which they all belong. Here's how to create a group:

1. Open the Users & Groups control panel.
2. Choose New Group from the File menu. A new double-headed icon appears, ready to have a name typed in to replace the default name "New Group". Type in whatever you want to name the group.
3. To include each user you want in the new group, drag the user's icon onto the group icon. Note that even though the user is added to the group, the user's icon stays in the Users & Groups window as well.
4. Open the group icon to see who is in the group. To remove a user from a group, drag the user's icon out of the group and throw it away.
5. When you open the user icon after a user has been added to a group, the names of the groups to which that user belongs appear in the user's Groups box.

   Remember that anyone who walks up to your system can change file sharing passwords and permissions. You may want to consider getting a System 7 compatible password locking screen saver.

System 7: What is Disk Cache?

What is disk cache?
This article has been archived and is no longer updated by Apple.
Disk cache is a static area in RAM set aside to help the Macintosh work more quickly and efficiently.

When a program asks for data from the disk (such as a part of a document), many times the next piece of data the program will need (such as the next part of the document) can be anticipated. Therefore, instead of transferring from disk to memory only the amount of data you are immediately working with, the system puts a larger amount (the size-of-disk-cache) of data into memory. This way, instead of spending the time to search for data on the disk again, the next piece of information will already be available. Disk cache works better on non-fragmented disks.

It may seem that the size-of-disk-cache should be configured to be quite large so that the need to search on the disk is greatly reduced. But this is not so because the memory allocated to disk cache cannot be used for opening more applications or documents. Thus, giving disk cache a huge amount of memory only makes that unavailable for use as RAM; it will not result in an increase in performance.

If the total memory of your system software appears to be very large under "About this Macintosh..." you should consider decreasing the memory allotted to disk cache. Open the Memory control panel and click the down arrow in the Disk Cache box.

System 7: Notes on File Sharing

Here is some information you need to know when you use System 7's Sharing option from the File menu to share a folder.
This article has been archived and is no longer updated by Apple.
Even after you have configured your Sharing Setup control panel, no one, not even the Guest account, can gain access to your system until you have configured folders or disks to be shared. File sharing won't happen until you give access to something to be shared--either folder or disk.

The appearance of a shared folder changes. When a folder has been configured to be shared, there will be network cables pictured at the bottom of the folder. When another user is using the folder, faces appear on the folder.

Once a folder has been shared, no folder above it in the disk hierarchy, or the disk itself, can be shared. If you try to do this, a dialog box will tell you the item could not be shared.

For example, if you share a folder on a hard disk, and then try to share the hard disk, the system will complain. You must turn off sharing on the folder before the system will allow you to mark the entire disk for sharing.

However, the opposite is not true. If folder A contains folder B, and folder A is shared, you may still share folder B. This enables you to set different permissions on folder B from those on folder A.

System 7: Permission Decisions for File Sharing

Once you have configured disks or folders for file sharing, you need to make decisions on file access permissions.
This article has been archived and is no longer updated by Apple.
First decide who is allowed to share on your system.

The center section of the Sharing dialog box determines the permissions of the files and folders within the folder or disk you are sharing.

There are three categories of users to define and specify permissions for:

- Owner is defined, by default, as the owner of the system as configured in the Sharing Setup control panel. The Owner name is a pop-up menu containing all of the users you have defined on your system. Defining someone else as the owner of a shared item will allow them to change all permissions pertaining to that folder or disk. You should change the owner of a folder or disk with care.
- The User/Group box allows either a user or a group to have the specified permissions set in the three check boxes.
- The Everyone category covers those users who are not defined in the Owner or User/Group category. This includes the user named Guest. By default, the Guest may log on to any system on the network without a password.

Therefore, for maximum security, always set the Everyone permission settings to off.

If the item you are sharing is a folder inside an already shared folder, you will have a "Same as enclosing folder" check box. Clicking this check box copies the same privileges of the enclosing folder to the currently selected folder.

- Once permissions are set, you can click "Make all enclosed folders like this one" to make the same privileges to all folders beneath the folder on which you are setting permissions.

Second, decide what those users and groups can share.

For each of the three categories -- Owner, User/Group, and Everyone -- you must decide what permissions you wish to grant.

- The permission See Folders indicates that users will have the icons of folders visible when they log on to your system. If this box is not checked, the corresponding user will not see any folders inside the shared item.
- The permission See Files is the same as See Folders, but pertains to files. Without this box checked the corresponding user category will not see any files. Users who can see a file can also copy it.
- When checked, the permission Make Changes allows the corresponding user to alter or throw away files and folders. Otherwise, the user will be able to open the file for viewing but not save any changes.

Once you have checked the permission boxes to reflect how you want your system configured, close the box in order for the changes to take place. Dialog boxes will appear, confirming your changes. Click OK to save your changes, or Cancel to disregard them.

Important: If you do not change any permissions when you select an item for sharing, the default configuration is to have the folder or disk open for view, change, and removal by anyone on your network.

System 7: Controlling Whether Users Can Change Their Passwords

How do I allow users to change their file-sharing passwords? Can I prevent them from changing their passwords?
This article has been archived and is no longer updated by Apple.

1. Open the Users & Groups Control Panel.
2. Open the User's icon. A dialog box appears.
   - To allow the user to change his or her own password, click the checkbox marked Allow User to Change Password such that an X appears there.
   - To prevent the user from changing the password, click the checkbox marked Allow User to Change Password such that no X appears there.
3. Close the dialog box, saving your changes.

Published Date: Feb 18, 2012

System 7: Disabling A User‘s Access to Your System

How do I disable a user's ability to connect to my system?
This article has been archived and is no longer updated by Apple.

1. Open the Users & Groups Control Panel.
2. Open the user's icon. A dialog box appears.
3. Remove the X from the Allow User to Connect check box.
4. Close the dialog box, saving your changes.

System 7: Virtual Memory and Disk Cache Contrasted

What is the difference between virtual memory and disk cache?
This article has been archived and is no longer updated by Apple.
Virtual memory uses disk space as if it were RAM, to increase the amount of memory the system believes it can use for running applications.

Disk cache tries to make the system run more efficiently with the memory available.

For more details, see the separate Tech Info Library articles on these subjects.
Published Date: Feb 18, 2012

System 7: TrueType Large Text Sizes

When using TrueType, is there a limit to how large text size may be?

This article has been archived and is no longer updated by Apple.

One of the benefits of TrueType is that characters can now be generated at any point size up to 32,000 points. However, almost all applications currently limit text size to 127 points. Also, some limit the number of size selections possible. Some applications do their own scaling for sizes above 60 points.

Macintosh: Calculating the Draw Rate

This article has been archived and is no longer updated by Apple.

Apple is often asked about the "draw rate" of Macintosh computers. If the question is "how many pixels per second?" the answer is "it varies." This is explained below. If the question is "how many vectors per second?" the answer is "the Macintosh doesn't use vector processing."

This article explains how graphic images are produced on both the Macintosh and on vector graphics terminals, and shows why there's no constant "draw rate" for the Macintosh.

Vector Graphics vs Bit-mapping

Vector graphic (line drawing) systems evolved from the basic plotter design that was first used for displaying computer graphics. To conserve memory (remember when memory was expensive?), only two points are stored for each line. The display image is calculated, during a screen refresh, by image generating hardware. Entire images can be stored on a mainframe or mass storage device and off-loaded to a terminal for processing.

The Macintosh uses a different technology, bit-mapping, which deals with an array of pixels mapped into RAM. A new image is displayed as fast as the bit-map RAM is updated; there is no need to calculate vectors. Storing the pixel information requires a great deal of memory. A monochrome image requires one bit per pixel; a color pixel requires several bits to specify its color (pixel mapping). Because a display like that of the Macintosh II contains 307,200 pixels (640 x 480), a minimum of 37.5 Kbytes is needed for a monochrome display. The same display using 8 bits per color pixel would need about 300 Kbytes.

Bit-mapped images, once stored, are updated at the speed of the vertical refresh rate, which is 66.67Hz on the Macintosh II video card. This means a full screen of video information (307,200 pixels) is displayed 1/66.67 times per second 14.5ms and a horizontal line (480 pixels) takes only 1/35,000 of a second .0285714ms (35KHz scan rate). (The actual number of pixels is slightly more as there are black borders where the beam is off.)

Calculating the Draw Rate

To calculate the time it takes to draw a given line, you must define where and when on a system the drawing of the line occurs. On a vector graphic system, the vectors are calculated (by a graphics generator) and sent to an image processor (video circuitry) for calculation of lines. Eventually they are converted by video circuitry to a display.

On a Macintosh, the "graphics generator" consists of the CPU and QuickDraw routines. The image is stored in video memory as a pixel map that is displayed by the video card circuitry. No further modeling is needed at the video card.

In both cases, to determine the time required to draw a line, a starting point and end point are needed. A number of other events can influence the timings and that will not accurately describe a working situation. This is not to imply that the two methods, pixel mapping and vector graphics, can or should be compared in this manner -- they're two different technologies. The benefit of pixel mapping lies in the finer control of each pixel for color or even video (analog) image processing at high speeds -- something not available through vector graphics processing.

Kinds of Graphics Generators

A graphics generator is a dedicated processor (or host) that calculates and

stores graphics information in some format, not necessarily similar to what will be displayed. A video processor is the circuitry that examines and converts graphics data into signals for the actual display. The examined data on vector graphics systems needs an added function of the video processor for the purpose of calculating the points between the end points as well as outputting the display signals.

Some of the possible methods (there are endless permutations) of generating graphics on a CRT:

- A graphics generator (dedicated or computer system) mixed with live video sources and even stored video sources with output to a display monitor and possibly a transmission and/or recording device.

- A standalone graphics system connected directly to a monitor.

- A host computer connected to a monitor. Usually, update times limit the practicality of using graphics terminals to alphanumeric or vector displays.

- A host computer connected to a graphics terminal that has its own processor to handle the graphics calculations.

- A host computer connected to a graphics controller that is connected to a monitor. The display information is fed to the controller for channeling to the needed device.

One of the options being used with small non-graphics dedicated computers is to place a graphics generator on a controller card with a video processor. The purpose of this is to free up the system CPU from the graphics handling tasks that it shares with the various system tasks.

The Macintosh II uses a host computer to graphics controller configuration with the storage of the RGB pixel information directly on the controller/video card. Other pixel maps can be created in the main memory of the Macintosh as well. This is useful for fast updates of the video card's pixel map. All logical maps or QuickDraw records are stored in main memory. This refers to the calculated pixels that are then transferred to the video card memory for updating of the display pixel map.

The Bottom Line

Now, to face the question of how long it takes to draw a given line. Because a Macintosh actually displays pixels, not lines, the question can't be answered with a simple number. The display times as noted above the display are themselves updated as fast as the Macintosh II CPU, running at 16Mhz, can calculate the line. This is still not display time, since it has to be combined with the time to transfer the calculated bits to the video card. The transfer time is not much of an issue when lines are the question, because very little information needs to be transferred. NuBus, the connection between the Macintosh II CPU board and the video card, can transfer 2.7 MBytes per second. Because a line in monochrome video mode might have 67 dots to the inch, only 67 bits need to be transferred. This doesn't take into account transfer protocol information and size of the data path on the NuBus.

The question then narrows down to "how long does it take QuickDraw to calculate a 1-inch line?" When you consider the other processes that must go on during an application:
- memory management
- vertical blanking interrupt processes
- interrupts from external devices
- the location of the line and its relation to other graphic entities
you begin to see why there is no single definition of the time it takes to draw a given line.

System 7: File Sharing Security

With System 7, guest access is automatically granted when File Sharing is activated.
This article has been archived and is no longer updated by Apple.
If guest access is not your wish, you must take actioin to limit access to shared items.

1) To eliminate anonymous access:
Deactivate "Guest Access"

2) To grant access to specific individuals:
Use the "User and Group" Functions

3) In all cases, when designating shared items:
Immediately configure permissions for "owner," "group," and "everyone."

Please note: An "item" is at minimum a folder and at maximum a volume (which may consist of an entire hard drive).
Published Date: Feb 18, 2012

System 7: Program Linking and InterApplication Communication

When do I need to turn on Program Linking? Is Program Linking necessary to send AppleEvents between programs?
This article has been archived and is no longer updated by Apple.
With AppleEvents, there are two possible configurations to take into account. The two communicating applications can be on the same computer, or they can be on different computers.

If the two applications are on the same computer, they simply use AppleEvents to communicate, with no other setup needed.

However, if the two programs are on different computers, permissions must be put in place to regulate the other system's ability to communicate with the programs on your system. When others are actively linking to your programs, your system may be slower to respond than usual.

You must turn on Program Linking to enable the InterApplication Communications (IAC) features of applications that are System 7-compatible. Program Linking is the switch that lets applications communicate with each other by sharing commands and data over AppleTalk networks. It provides security measures that prevent unauthorized use of programs and data from remote computers. To activate IAC, permission must be granted at System and Application levels.

How to Turn On Program Linking

To respond to events from remote computers, you must explicitly let network users link to your computer. To do this, follow these steps:

1) Open the Control Panel folder.
2) Open the Sharing Setup Control Panel.
3) Enter your name, password, and your computer's name.
4) Click the Start button for Program Linking.

The Sharing Setup Control Panel then states "Program Linking is on. Click Stop to prevent other users from accessing shared programs." To prevent other computers from initiating sessions, click Stop underneath Program Linking.

Selecting Specific Applications

Here's how to select specific applications:

1) Select an application from the Finder.
2) Choose Sharing from the File menu.
3) Click the Allow Remote Program Linking checkbox.

What Else You Must Do

In addition to letting remote users initiate conversations between applications via Program Linking, you must:

* Permit physical access to their programs and data by enabling File sharing from the Sharing Setup Control Panel
* Choose which other users to interact with via the Users and Groups Control Panel.

To establish access for other users and guests, follow these steps:

1) Open the Users & Groups icon in the Control Panels folder.
2) To specify a particular new user, choose New User from the File menu.
3) Type the user's name and password.
Published Date: Feb 18, 2012

System 7: Program Linking versus Publish and Subscribe

How does publish and subscribe differ from program linking?
This article has been archived and is no longer updated by Apple.
Publish-and-subscribe uses a transition file called the edition file. In program linking, the two programs talk directly to each other.

You probably would publish a report generated from a database, but not the cells of the database. For example, a word processor gets the top ten salespeople from a database.

Publish and subscribe, by which a change in one document effects a change in another document, has some of the flavor of program linking. However, it is important to note the differences, and corresponding strengths, of each feature.

The publish and subscribe feature is good for allowing programs (and their documents) to share data, while program linking using AppleEvents allows programs to communicate with each other--not only to send and receive data, but also to provide services to and request services from the other program.

Publish and subscribe are used when:

- you would otherwise copy and paste the same data;
- the data involved will probably not be changed by the users who subscribe to it;
- the data is likely to be widely distributed--as in a large writing project;
- one document needs data from several other documents.

Applications use AppleEvents to:

- get data from another program if the details of the request change slightly each time;
- get another program to manipulate and return a set of data;
- configure and control a variety of programs.

System 7: Program Linking versus File Sharing

How is program linking different from file sharing?
This article has been archived and is no longer updated by Apple.
File sharing and program linking both provide the ability to manipulate files, but program linking is a more comprehensive approach to the task.

File sharing strengths are based on the accessibility of files to others on your network. File sharing can make folders, hard disks, and CD-ROMs available to others. Users manipulate the files as if the files were local to their systems.

Program linking, on the other hand, is an automated programming effort in which applications are working with and manipulating other applications.

In configuring program linking, one element is similar to file sharing. To make a program available for linking, you choose Sharing from the File menu. There is never a conflict between the two because you may share only disks or folders, and you may link only application programs.

NetWare for Macintosh 3.0

On February 11, 1991, at NetWorld in Boston, Novell, Inc. announced NetWare for Macintosh 3.0, a complete AppleTalk protocol-suite implementation that fully integrates Macintosh desktop systems into the NetWare v.3.11 network computing environments (formerly named NetWare 386 v.3.x).

Apple does not endorse or recommend any third-party products mentioned in this article, which was first published in AppleGram, May 1991. This article has been archived and is no longer updated by Apple.

NetWare for Macintosh 3.0

NetWare for Macintosh 3.0 provides file and print services to Macintosh clients in a NetWare environment using the AFP and PAP, AppleTalk protocols. This means Macintosh users connect to a NetWare v.3.11 server in the same way as they connect to any other AppleShare file server--by logging in and selecting volumes through the Chooser. Printing to a PostScript printer connected to the Novell server is also done in the familiar Macintosh way.

NetWare for Macintosh 3.0 provides Network Administrators easy and complete solutions for integrating Macintosh systems into NetWare v.3.11 environments. The implementation of the full AppleTalk stack as a set of NetWare Loadable Modules (NLMs) provides the architecture necessary for integrating Macintosh with other Novell services, such as NetWare Communications.

Macintosh Integrates Into Multivendor Networking Environments

NetWare for Macintosh 3.0 is an important milestone for Macintosh users in multivendor networking environments. Macintosh users can now share resources with DOS, Windows, OS/2 and UNIX desktops when in an advanced networking environment. NetWare for Macintosh 3.0 also offers enhanced security, fault tolerance, and high performance to all client desktops. Macintosh users in this large network environment will find accessing these remote network resources as easy as accessing their local file servers and printers.

Macintosh Administration Capabilities

Additional features of NetWare for Macintosh 3.0 include:

- Macintosh client software that allows any Macintosh user on the network to control NetWare capabilities such as setting rights, assigning trustees, managing print queues and sending messages to other networked users
- Macintosh client software that allows designated Macintosh users to perform administrative tasks such as adding or deleting users and groups, assigning passwords, and setting file attributes
- Support for AppleTalk Phase 1 and Phase 2

AppleTalk Routing

NetWare for Macintosh v.3.0 includes an AppleTalk Router as one of its core technologies. That means that users can share AppleTalk resources on different AppleTalk networks that are connected by the server.

NetWare for Macintosh 3.0

AppleShare products are the ideal solutions in environments that are primarily Macintosh and where the network services required are primarily file and printer sharing. NetWare for Macintosh uses the same AppleTalk protocols and user interface model as Apple's AppleShare products. Using Apple's model, Novell is able to integrate many of the advantages of AppleShare into a more advanced networking environment where multivendor connectivity, enhanced security, fault tolerance, and high performance are critical user requirements.

Apple, AppleShare, AppleTalk, and Macintosh are registered trademarks of Apple Computer, Inc.

UNIX is a registered trademark of UNIX Systems Laboratories.

System 7: Running the Compatibility Checker

How do I run the System 7 Compatibility Checker and how does it work?
This article has been archived and is no longer updated by Apple.
The Compatibility Checker is a HyperCard stack that checks the programs on your system against a database of applications contained within the stack. It then reports the compatibility status as provided by developers. Note that if your software is brand new, the Compatibility Checker may flag it as incompatible simply because it doesn't recognize the new version number. Also, check that you have version 1.1 of Compatibility Checker, which adds much new software to the list and updates existing information.

Here's how to use it:

Step One
Open the Before You Install stack.

Step Two
Click Compatibility Checker.

Step Three
Click the Set Up button.

Step Four
Select the disk(s) to check.

Step Five
Click the Start Checking button.

The stack starts checking: first for viruses, then for applications, INITs, cdevs, rdevs, and DAs. Depending on the number of items, this may take a while. The stack displays progress on a bar chart.

Step Six
Once the check is complete, you are given a choice of moving any potentially incompatible items out of your System Folder. Click the Move Items button if you want the Compatibility Checker to move the items for you. Click the Don't Move Items button if you prefer to move them yourself.

Step Seven
The program provides a report, which lists all of the items checked and their compatibility status.

Step Eight
Click the Print Report button to print the report, or the Save Report button to save the report to disk.

Step Nine
Click the Quit button to exit the stack.
Published Date: Feb 18, 2012

System 7: Activating Finder Windows

I've noticed that directory windows sometimes become active when I release the mouse. Is this a new feature of System 7?
This article has been archived and is no longer updated by Apple.
Yes. This is an enhanced feature of System 7. It prevents active windows from getting in your way while you are moving icons.

To make a window active, simply click the window. If you click an icon, the window activates when you release the mouse button. If you click elsewhere in the window (not an icon), the window activates when you press the mouse button.

This is different from System 6, in which windows are always activated on mouse-down.

This allows you to move an icon from an inactive window to another window without having the inactive window become active and possibly cover other items on your desktop.

Moving an icon from an inactive window to another inactive window leaves the currently-active window active. This way you can move an icon from an inactive window to an inactive window without making either active. Also, if you want to move a window without making it active, hold down the Command key and drag the window (by clicking in the title bar).
Published Date: Feb 18, 2012

System 7: Locating the Original of an Alias

How can I find the original of an alias?
This article has been archived and is no longer updated by Apple.
The Finder can show you both the original and its pathname. Follow these steps:

1. Select the alias.
2. Choose Get Info from the File menu. The path to the original is listed after the heading "Original" in the Info window.
3. Click the Find Original button. A Finder window containing the selected original opens.

Published Date: Feb 18, 2012

System 7: Findable Attributes

Can I use the Finder's Find command to search for files by attributes?
This article has been archived and is no longer updated by Apple.
Yes. The Find command seeks out the file you want to locate and selects it based on a variety of file attributes, allowing you to refine your searches to be as specific as you want. For example, you can find all the files created between May 21 and July 27 that are larger than 15K.

You can search for files by:

- Name
- Size
- Kind
- Label
- Date Created
- Date Modified
- Version
- Comments
- Lock

You can find files using any or all of the criteria above, singly or in combination. (**Warning:** rebuilding the desktop removes all comments on a drive.) If you want to search using multiple attributes, just do your first search, checking the "all at once" box. Then, with all the selected files still highlighted, do another search for your secondary attribute. You may do this until you narrow the search down to the desired level.

The Search pop-up menu near the center of the dialog box lets you search on any currently mounted disk or server.

The choices available in a pop-up menu depend on the contents of the pop-up menu(s) to its left.
Published Date: Feb 18, 2012

System 7: Customized Installation

How do I do a customized installation of System 7?
This article has been archived and is no longer updated by Apple.
You may want to custom install:

- To limit the installation of certain features (for example, File Sharing)
- To minimize the amount of disk space the system occupies.

The following instructions are for an installation from floppy disk. (Installation from CD-ROM is similar, except that you don't have to swap disks.)

Step One
Restart your Macintosh with the Install 1 disk in the floppy drive.

Step Two
Open the Installer application on the Install 1 disk.

Step Three
Click OK to proceed past the welcome box.

Step Four
Verify that the disk named on the Installer screen is the drive on which you want the software to be installed. Click Switch Disk if you want to install on a different drive.

Step Five
Click the Customize button.

The custom installation screen appears, showing the parts of the system software and a choice of standard or minimal system files for each model of Macintosh.

Step Six
Scroll through the list of items and Shift-click the ones you want to install. As you select items, their names appear in the lower-left portion of the dialog box.

Step Seven
Click Install to install this software configuration onto the selected disk.

The Installer will decide which disks are required, and then prompt you to insert them as needed.

Step Eight
Click Quit when you see a message indicating that the installation was successful.

Step Nine
Click Restart in the dialog box that appears when you quit the Installer.

Note: When installing on an external hard drive that might be used on another system, it's best to choose the "For any Macintosh" option.

System 7: Keyboard Navigation

Article Change History

08/24/92 - REVIEWED
* For technical accuracy.

System 7 provides shortcuts to navigate around your files. This article tells how to use these techniques.

This article has been archived and is no longer updated by Apple.
Here's where you can use navigation shortcuts:

* In Finder windows

* In the Chooser

* In the list displayed in a directory dialog box

* On the desktop

Typing any alphabetic character moves the selection to the first item whose name begins with that character, or the next closest successive character in the alphabet.

For example, if you type the character "s", your selected icon may be the System Folder, if no other files or folders come before the word System in alphabetical order.

The speed at which you type in the characters is important. If there are several files beginning with the character "s", you can type more of the name to select the desired icon. If you type too slowly, though, the system will think you want an icon beginning with a letter other than "s".

Pressing the Tab key moves the selection to the next icon in alphabetical order. Pressing Shift-Tab moves the selection to the previous icon in alphabetical order.

Finally, the arrow keys select the next icon in the direction of the arrow.

System 7: How to Use Control Panels

This article explains how to use control panels in System 7 to customize your system.
This article has been archived and is no longer updated by Apple.
In System 7, control panels open as though they were applications. Just double-click their icons, and you have access to the control panel you want.

An alias for the Control Panels folder is in the Apple Menu Items folder, making the control panels even easier to use. The alias in the Apple menu also provides interface compatibility for System 6.0.x users. You can have more than one Control Panel open at the same time.

To install a new control panel, simply drag its icon onto the System Folder icon. It will automatically be put into the Control Panels folder. (You can move control panels directly to the Control Panels folder yourself, of course.) Control panels can be put anywhere for quick access: on the desktop, in a folder, in the Apple menu, and so on. But if a control panel has INIT code that needs to be loaded at startup, it must be in the System Folder or the Control Panels folder.

Some functions that once were adjustable only with ResEdit, can now be modified by control panels. The settings you can adjust in the control panels include, but are not limited to:

- Font and type size used by the Finder for icon names
- Icon size and attributes listed in list views
- Icon layout in icon views
- Memory control
- Pattern and colors of the desktop
- Date, time, and display of time
- Speaker volume and alert sound
- Relative distance the pointer moves on screen when you move the mouse
- Relative positions of multiple monitors
- Number of colors or shades of gray displayed
- Disk drive to be used for startup (startup volume)
- Label names and colors available for icons
- Special aids for using the keyboard and mouse
- File sharing setup and program-to-program connections
(available to Macintosh computers on a network)
- Remote user access

System 7: Removing Fonts and Sounds

Article Change History

08/25/92 - REVIEWED
* For technical accuracy; edited.

A new feature of System 7 allows you to remove fonts and sounds by dragging the resource icon out of the open System file. This article details how to do this.

This article has been archived and is no longer updated by Apple.
Fonts and sounds are removed by dragging them out of the System file.

1) Quit all programs that are currently open. You'll get an error message if you try to remove a font or sound when any programs (other than the Finder) are open.

2) Open the System file. This may take a few moments if the file is large.

3) Select the icon of the font or sound you want to remove.

4) Drag the icon out of the System file window. To discard the font or sound, drag it into the trash. To save it for future use, drag it anywhere outside of the System file.

Published Date: Feb 18, 2012

System 7: System Sounds

How do I recognize a sound file? How do I play a sound when it is installed in the System Folder?
This article has been archived and is no longer updated by Apple.
Sounds are identified by their unique icons. Under System 7, you can play a sound by double-clicking the sound file, whether it is inside the System file or loose on the disk.

Sounds installed in the System file must be sound resources, in particular, resources with the type "snd". (You can check the resource type by using ResEdit.) If you are able to drag a sound file into the System file, then it is in the proper format. There are several third-party sources for sound resource conversion applications.

To change the system alert sound:

1) Open the Sound control panel. This is usually located in the Control Panels folder within the System Folder, or accessed via the Control Panels menu item in the Apple menu.

2) Click the name of the sound you want. The sound is played.

3) Adjust the volume, if desired. The alert sound is played to demonstrate what it sounds like at the new volume.

Warning: The instructions in this article refer to using ResEdit. Apple Computer, Inc., is not liable for any damage done to your software through the use of ResEdit to alter software.

System 7: Changes to the System File

In System 6.0.x, you had to use the Font/DA Mover to open the System file. In System 7, the System file behaves as an ordinary folder that can be opened from the Finder.
This article has been archived and is no longer updated by Apple.
To open the System file, double-click it. When open, the System file displays all of the fonts, keyboard layouts, and sounds installed in it -- as though it were a folder. While fonts and sounds are actually resources, they are treated as though they were simply files within a folder. (Because resources are special files, aliases cannot be substituted for them.)

You can double-click any font to see a sample of that font. You can double-click any sound to hear the sound.

Many of the functions that used to be contained in the System file have been moved to specific control panels. Modifying such things as icon layout no longer requires manipulation of the System file with ResEdit or other tools.

TA46825_System_Edition_Files_(TIL08384).pdf

System 7: Edition Files

Article Change History

09/22/92 - REVIEWED
* For technical accuracy.

This article discusses operations performed with edition files.

This article has been archived and is no longer updated by Apple.
You, the user, make the choice of when a publisher will update its edition file. Generally, the two choices are to update the edition either:

- automatically when the file containing the publisher is saved, or

- manually when the Send Edition Now button is pressed from the Publisher Options dialog.

Different applications may have different options. Links between publishers and their edition files are effective until they are specifically canceled. If an edition file is thrown away without canceling the link, a new edition file will be created when the document containing the publisher is saved.

You cannot directly change the edition files, though you can open them to examine their contents. When you open an edition, the contents of the file are displayed and you get a dialog box asking if you want to open the publisher, presumably to make changes.

You also make the choice of when a subscriber will receive edition updates. Again, there are generally two options; a subscriber may update:

- automatically when the file containing the subscriber is opened, or

- manually when the Get Edition Now button is pressed from the Subscriber Options dialog.

If you cancel a subscriber, the current information will remain, but it will no longer be updated. If a subscriber's linked edition file has been removed, a warning dialog is issued.

The System software keeps track of which edition files are linked to which publishers and subscribers, in the same way it keeps track of alias files. If an edition file is moved, the system updates its pathname. Making a copy of an edition file does not copy its linkages, however.

Publishing is different from program linking. Publishers update an intermediate file, and subscribers update from that intermediate file. In program linking, an application sends commands (AppleEvents) directly to another application; there is no intermediary.

System 7: Using Stationery

Article Change History

08/18/92 - REVISED
* Combined two articles into this one.

What is stationery? How can I use it? Does it work with all applications?

This article has been archived and is no longer updated by Apple.
Stationery is a System 7 feature with which you create "template" documents. For example, if you have a memo form that you use frequently, you can create a stationery document that gives you a fresh version of the memo every time you open it.

Stationery works with all applications. Some applications are stationery-aware. That is, you can specify whether a document should be treated as stationery when you first save the document using the "Save As..." command. Although other applications are not stationery-aware, there is another way to create a stationery document.

How to Create a Stationery Document

Follow these steps:

1) Create your template document in your application. For example, you might have a document that has "From:" "To:" and "About:" lines.

2) Save the document to your disk.

3) Switch back to the Finder (desktop).

4) Select the document's icon.

5) Choose Get Info from the File Menu.

6) Click the box marked "Stationery" in the Get Info window.

7) Close the Get Info window.

When you open the stationery document, you get a copy of the document for your use.

A stationery pad can be opened like any other document -- by double-clicking its icon, by selecting it and then opening it from the File menu, or by opening it from within an application.

When a stationery pad is opened for an application that supports this feature, a new file with the title "Untitled" is created. This file is a copy of the stationery pad, containing all the formats and information of the original. You make changes to the "Untitled" document, naming it when you save the new document. The new document is saved as a regular document -- not as a stationery pad -- unless you specify otherwise.

For applications not yet supporting the stationery option, you name the new document when you open the stationery pad. Double-click the icon of the stationery pad you want to open. A dialog box appears asking you to name the document. Type a name for the new document. After saving the document, you can then proceed to make the desired changes.

You can make changes in a stationery pad by turning off the "Stationery

pad" attribute through the Info box, making the desired changes, then turning the attribute back on.

System 7: How to Customize the Puzzle

Article Change History

08/25/92 - REVIEWED
* For accuracy.

Can I customize the color Puzzle in System 7's Apple menu?

This article has been archived and is no longer updated by Apple.
Yes. Start by making a duplicate of the Puzzle, so that after making a custom Puzzle, you'll still have the original.

1) Put a graphic, one that is about the same size as the Puzzle itself, on the Clipboard.

Some possible sources:

* a HyperCard or MacPaint bitmap

* a screen dump or other PICT copied using System 7's new TeachText program.

2) Open the Puzzle, and choose Paste from the Edit menu. The graphic is copied from the Clipboard into the Puzzle, and scrambled.
(To see the graphic unscrambled, choose Show Clipboard from the Finder's Edit menu.)

System 7: Starting Filenames with Space Character

Article Change History

09/11/92 - REVIEWED
* For technical accuracy.

Earlier versions of Macintosh system software didn't allow filenames to begin with a space character, but System 7 does allow this.

This article has been archived and is no longer updated by Apple.
If you begin a filename with a space character, then use "View by Name", that file will appear at the top of the list. This is a good way to force important files to the top of the alphabetical list.

RS-232: Applefile III and QuickFile III

This article has been archived and is no longer updated by Apple.
Applefile will not recognize an .RS232 driver configured as a character read-write device ($63). If .RS232 is changed to a write only device ($41), Applefile recognizes it and shows it under the printers available. If an RS-232 device is a write only device, the handshaking, XON/XOFF or ETX/ACK, will still function. XON/XOFF and ETX/ACK are not data per se and will be treated as handshaking. Therefore, a driver will still be found if it is configured as a write only device such as a printer, since the driver does not have to READ the printer. These same modifications will allow QuickFile III to use the .RS232 driver.

Mac OS: Changing Sequence of Apple Menu Items

I have installed so many desk accessories in my Macintosh system that my Apple menu is longer than my monitor is high. Further, some of the menu items I use most often are near the bottom of the list, and scrolling to them is annoying. Is there a way to force a few of my menu items to the top of the alphabetical list--without renaming them?

This article has been archived and is no longer updated by Apple.

There is an easy way to force a few of your menu items to the top of the alphabetical list without renaming them.

For example, if you change "Scrapbook" to " Scrapbook" (with a leading space), then it appears in the Apple menu ahead of "AppleCD Audio Player" and "Chooser".

In the Finder, open your System Folder, then your Apple Menu Items folder, and change the names of the menu items as you would any other filenames.

You might also want to experiment by putting various punctuation symbols at the beginning of the items in your Apple menu to see how this affects the sequence. If the menu is cluttered, make an empty folder named simply with a row of hyphens, or any other character, and use it as a divider with leading spaces to position it appropriately between, folder aliases and application aliases in your menu.

LattisNet System 3000

This article describes the LattisNet System 3000, manufactured by SynOptics

This article has been archived and is no longer updated by Apple.

SynOptics' Network Utility Architecture defines local area networks as utilities, and combines three elements: connectivity, internetworking and network management. Physical layer connectivity includes access methods such as Ethernet, Token Ring and Fiber Distributed Data Interface (FDDI). Internetworking, used in larger networks, refers to bridges and routers. Network management systems keep complex networks running reliably and efficiently.

The LattisNet System 3000 provides integrated LAN data Communications, internetworking and network management functions within a single network utility. Modular components satisfy a variety of network needs.

System 3000 concentrators provide a common platform to support the Network Utility Architecture. The Model 3000 Premises Concentrator and the Model 3030 Department Concentrator hold the modular components that provide basic connectivity, integrated bridging, and network management utility functions.

A modular backplane supports IEEE 802.3-compatible Ethernet at 10 megabits per second (MB/s) and IEEE 802.5 Token Ring at 4MB/s and 16MB/s. System 3000 concentrators offer increased LattisNet module and port density to support more nodes with less equipment.

System 3000 host modules offer network connectivity. Ethernet host modules provide media flexibility by offering twisted pair and FOIRL fiber optic interconnections. Token Ring host modules operate over twisted pair wire. Auto-partitioning functions disable port connections under specific Ethernet fault conditions to ensure network integrity. Front-panel LEDs indicate link status, partitioning, and network management activity. System 3000 Token Ring ring-in/ring-out modules connect to other Token Ring-compatible devices to create larger LANs. Ethernet retiming modules help satisfy the IEEE 802.3 repeater function.

The bridge hardware and bridge management software provide integrated modular local bridging capabilities. LattisNet Ethernet local bridge modules have attachment unit interface (AUI) and fiber optic connector options to interconnect network segments and form single, transparent LattisNet networks. LattisNet local bridges filter operator-defined data packets and include a Spanning Tree Algorithm function which provides a redundant network path for rapid recovery from bridge or link failures.

The network management capabilities include planning, data monitoring, problem determination and fault isolation from a centralized console. Network management modules offer AUI and fiber optic connector options. Real-time network information is displayed graphically as a network hierarchy with Expanded Views of individual concentrators. A report generator captures and stores specific data on request. LattisNet Network Management permits individual port partitioning. It also allows the network manager to set module- and port-level activity and fault thresholds based on media access control (MAC)-level parameters and statistics.

LattisNet products implement IEEE 802.3-compatible Ethernet over twisted-pair wire and fiber optic cable. They also support both IEEE 802.5 Token Ring and 802.5-compatible networks over twisted-pair wire.

You can find the phone number and address for SynOptics in a separate article in the Tech Info Library.

Network Guidelines

This article offers some guidelines for getting the best service from a network.

This article has been archived and is no longer updated by Apple.

- All devices on Ethernet need to be using the Phase II EtherTalk driver.

- Be sure that computers using Ethernet have EtherTalk cards, revision L or later.

- If you are using Ethernet, don't crimp or tightly wrap the cables. This degrades network performance.

- Install Responder in the System Folder of any Macintosh running 6.0.x. (Responder is built into System 7.)

- All Macintosh IIfx computers must have the Macintosh IIfx Serial Switch INIT in the System Folder. Set the Serial Switch to compatible mode to work with dial-up-connection applications and the old Star Controller model.

- Be sure all System 7 users have the same version, and no versions older than Beta 4. Inter*Poll can help find out what versions are in your network group.

- Don't daisy-chain any devices. This creates a heavy load on the network that often exceeds the capacity of the specifications.

- All spoolers must be on the same network (not just zone) as the LaserWriter they spool to.

- Use Inter*Poll to observe the workgroup use and traffic patterns on the network.

- Check the types of software used on the network. A beta-test environment can degrade network service.

System 7: EtherPort Driver Compatibility

Article Change History

12/10/92 - UPDATED
* To give current version information.

I need a list of System 7 compatible drivers for EtherPort Ethernet cards available.

This article has been archived and is no longer updated by Apple.
Shiva no longer supports Etherport products. Eagle Technology supports these products.

Here's a list of the compatible driver versions:

Product	Current Version	Minimum Needed for System 7
EtherPort II (Nubus card 7-8 inches long)	4.2	4.2
EtherPort 2.6 (Older Nubus Card 12 inches long. Not 32-bit compatible)	2.6	2.6
EtherPort SE	2.6	2.6
EtherPort SE30	4.2	4.2
EtherPort SI	4.2	4.2
EtherPort LC	4.2	4.2

No company supports the EtherPort SC (SCSI unit).

MacTerminal and LisaTerminal: Line feeds after carriage returns

This article has been archived and is no longer updated by Apple.

It is the job of the sending device to provide line feeds after carriage returns if necessary. For example, when you're using your Macintosh to send text to another Macintosh, you must select New Line (a Terminal Settings option from the Settings menu); otherwise, the user on the other end will receive all the incoming text overwritten on one line.

In LisaTerminal, set Auto New Line to "on" to SEND a line feed after a carriage return. Auto New Line is an option in the Computer Compatibility box located in the Setup menu.

Visual Almanac LaserDisc Product

This article describes the Visual Almanac, a product available from Optical Data Corporation.

This article has been archived and is no longer updated by Apple.
The Visual Almanac is an interactive multimedia kit that combines a videodisc with the Macintosh computer running HyperCard.

It features three segments:
- a collection of 7,500 moving and still images and sounds
- a composition workspace for manipulating text, images, and sounds
- 14 student activities in science, the arts, social studies, and mathematics

The package contains a 2-sided LaserDisc, a CD-ROM disc, a cable to connect the Macintosh to several different popular LaserDisc players, and documentation.

Call Optical Data Corporation for an order form. You can find the phone number and address in a separate article in the Tech Info Library.

System 6.0.6: Don‘t Use It

How come I shouldn't use System 6.0.6 on ANY Macintosh? And why should I use System 6.0.7 only on newer Macintosh computers?

This article has been archived and is no longer updated by Apple.
System 6.0.6 has compatibility problems with the new Macintosh computers. System 6.0.6 was pulled from production and replaced by System 6.0.7. There are a few versions of System 6.0.6 floating around that were sent out before the software was pulled from production.

You should use System 6.0.5 (or System 7) on most Macintosh computers made before the Macintosh Classic, Macintosh LC, and Macintosh IIsi. System 6.0.7 has features in it that only benefit newer Macintosh computers. This does not mean that you can't use System 6.0.7 on older products, it just means that it is not the recommended system.

Display Card 824 GC: Compatibility With Other Video Cards

How do I use a Macintosh Display Card 8*24 GC in conjunction with a third-party video card? Specifically, I'm trying to use a RasterOps Video ColorBoard 364 with the Macintosh Display Card 8*24 GC. With both cards in a Macintosh, only one card works -- depending on which slots I've put the cards in. The card that's in the slot closest to the power supply is the one that's recognized, while the other card doesn't work at all.

RasterOps says that the Macintosh Display Card 8*24 GC might not be releasing control of the bus to other graphics cards. Is this what's happening?

This article has been archived and is no longer updated by Apple.
The card nearest the power supply becomes the "bus master". If your Macintosh Display Card 8*24 GC is in the bus master slot, it will take control of the bus and prevent another card with a processor on it to run.

If your third-party card is in the bus master slot, the third-party card may or may not release control of the bus, depending on its design.

Essentially, you can have only one accelerator card running at a time. If you turn the acceleration of the Macintosh Display Card 8*24 GC off, you should be able to use both video cards.

TA46841_AUX_Programmers_Tools_and_X_Windows_(TIL08409).pdf

A/UX 2.0: Programmer‘s Tools and X Windows

1) What is the minimum-sized A/UX partition? (Can A/UX be totally installed on a SyQuest Drive?)

2) What do the Programmer's Tools include?

3) Is the X Window package included with the Programmer's Tools?

4) Can X Windows applications be created with the X Window package, or is another programming tool necessary?

This article has been archived and is no longer updated by Apple.

```
1) The partition that contains the complete A/UX is 70+ MB.  If you are
  willing to remove utilities, you can get it down to 50+ MB.

2) The Programmer's Tool Kit includes the standard AT&T set of utilities.

3) X Windows is sold separately.

4) Yes.  It includes libraries for X11R3.
```

AppleShare: Finder Copying Causes ID=1 Errors

When I do a Finder copy of files onto my AppleShare server folders, why do I get an ID=1 error?

This article has been archived and is no longer updated by Apple.
This is because you're putting information onto your server without AppleShare being "aware" that you've done this. When you put information on the hard drive of the server with AppleShare off, the AppleShare PDS file doesn't update correctly.

You need to run the AppleShare Admin program and verify the volume to update the PDS file. A way to prevent this is to copy files to your server over the network. This updates the PDS file as your files are copied.

AppleCD SC: How To Use with AppleShare

How do I use an AppleCD SC Drive on an AppleShare Network?

This article has been archived and is no longer updated by Apple.
Here are the steps:

1) Install the AppleCD SC driver on the AppleShare Admin diskette and the file server volume.

2) Start up from the AppleShare Admin diskette and use the "Prepare volume for use with AppleShare" command.

The name of the CD-ROM will appear and AppleShare will create a parallel directory structure for the CD. That's all it takes.

Published Date: Feb 18, 2012

AppleShare: Problems Installing with System 6.0.5

I'm trying to set up an AppleShare file server on a Macintosh SE/30 with System 6.0.5. I used the Installer on the AppleShare File Server Installation disk, choosing only the AppleShare installation (in other words, not using the Macintosh System installation option). So far so good.

However, when I attempt to load files from the Server Administration disk, I get the message that the System file on that disk is not a recent enough version (it was System 6.0.3).

This article has been archived and is no longer updated by Apple.
You need to run the Installer from a System 6.0.5 disk and create a new floppy using the option to install minimum system files for the Macintosh SE/30. After you create that startup disk, drag the AppleShare Admin program onto that floppy. You'll then be able to start up from the floppy and run the AppleShare Admin program.

Published Date: Feb 18, 2012

Apple IIGS: How To Start Up from Floppy Disk Using Aristotle

I'm using Apple IIGS computers with a menu management program and a Macintosh file server. The menu management program is set as the startup application. I'm not using a network startup or "boot disk" and I don't want to. Here's my setup:

Slot 1 AppleTalk
Slot 7 AppleTalk
Startup AppleTalk

I don't want to reconfigure my Control Panel just to be able to start up from a floppy disk. But with my current settings, if I press Control-Open-Apple-Reset, the floppy drives don't do anything.

I need a way to start up from a floppy without changing any of my Control Panel settings. Can I create a program in BASIC and put it in my menu management program? Would this BASIC program, when selected, cause my Apple IIGS to start up from the floppy drive?

This article has been archived and is no longer updated by Apple.
There are two ways to do what you want:

First Method
---
1) Interrupt the boot process by pressing Control-Reset while the system is booting. This will give you the "]" prompt.

2) Type "PR#6" to tell the computer to start up from the controller card in slot 6. (If you're starting up from a 3.5-inch floppy disk, use 5 instead.)

Second Method

To do the same thing through Aristotle, simply create a BASIC program with the following line:

```
10 PR#6
```

Save this program and set it up as an Aristotle menu item. The problem here is that you must start up all the way into Aristotle before you'll get back to the ability to boot from a local drive. Control-Reset will give you the ability to boot from a local drive much sooner.

Published Date: Feb 18, 2012

Macintosh: Desktop Manager

I have more than 1000 files on my Macintosh hard drive and am running System 6.0.5. I have an ongoing problem with fragmentation and am constantly optimizing, formatting, or reinstalling all data on my hard drive. I've read that the Desktop file was designed back in the 400K floppy days. Should I put "Desktop Manager" in my System Folder (from the AppleShare disk)?

This article has been archived and is no longer updated by Apple.

The Desktop file is capable of managing 64,000 files. The Finder really bogs down if you have more than 800 files per folder level. The Desktop Manager is not needed for only 1000-2000 files. On the other hand, it won't hurt to have it and it might increase the reliability and even make some functions more efficient.

Macintosh: Dayna Drive for Transferring MS-DOS Files

I want to transfer MS-DOS files from 5.25-inch disks to my Macintosh. Is there any way of connecting an external 5.25-inch disk drive to a Macintosh SE/30?

This article has been archived and is no longer updated by Apple.

Yes. Dayna Communications makes a drive called the Dayna File that connects through the SCSI port.

For more information, search the Redgate Buyer's Guide icon under "Dayna".

Published Date: Feb 18, 2012

EtherTalk 2.0.2: Where to Find ENET Driver

Where can I find an EtherTalk 2.0.2 driver?

This article has been archived and is no longer updated by Apple.
The .ENET driver resource file installs as part of the System file when the EtherTalk driver is installed using the Network Products Installer disk that is shipped with all new computers.

Remember, there are two different drivers: one is the actual EtherTalk driver, which you can see in the System Folder; the other is the .ENET driver, which you cannot see.

If you have an older version, 2.0.2 can be acquired from AppleLink or any Apple Authorized Dealer.

TA46850_Monitor_II_Phosphor_(TIL00842).pdf

Monitor II: Phosphor

This article has been archived and is no longer updated by Apple.
The decay time for the P-31 phosphor is 70 microseconds from 100% to 10%.
That correlates to about a 77 microseconds decay time to 0%.
This knowledge may be useful to, for example, research labs conducting
visual perception experiments that include extremely rapid presentation
of visual stimuli.

EtherTalk: How To Install for AppleTalk Phase 2 Compatibility

Where can I find a copy of the EtherTalk Interface driver that's compatible with AppleTalk Phase 2?

This article has been archived and is no longer updated by Apple.
You need to run the Network Product Installer disk and tell it you want to install EtherTalk. When it asks for the disk, insert the EtherNet Installer Disk 2.0.1. This will install the AppleTalk Phase 2 drivers.

Macintosh IIfx: NuBus/SCSI Speed

I'm a little confused about SCSI data transfer. Several sources say that the speed of the SCSI port on a Macintosh IIfx is between 1.4MB and 4.0MB per second. I know that synchronous mode is needed to obtain the higher rates, but if a drive is only rated at 13 kilobytes per second with an access time of 11.9 milliseconds, how do I get rates of 2 or 3 megabytes per second?

Also, if the NuBus slots are rated at 10MB per second, wouldn't I gain by using these slots?

This article has been archived and is no longer updated by Apple.
It's not the access time of the drive that matters, but rather the sustained transfer rate. Any SCSI hard drive that can sustain transfer rates above 1.25MBps will operate faster on a Macintosh IIfx compared to any other Macintosh system. None of Apple's present drives take advantage of this potential.

If a SCSI card was designed to operate with NuBus it would limited to 10MB per second, which is faster than the Macintosh IIfx's 3MB per second spec, but much faster that any of our other drives, at this point.

TA46853_Apple_IIGS_System_Software_after_Requires_K_RAM_(TIL08424).pdf

Apple IIGS: System Software after 4.0 Requires 512K RAM

I have a 256K Apple IIGS. What's the latest Apple IIGS system software version for a 256K Apple IIGS without a memory expansion card?

When I try to load System 4.0 through 5.0.2, I get a "RAM Disk Too Large" error message. When I go into the Control Panel, RAM disk is set to 0K, 84K RAM in use, and 171K free. Why is this?

This article has been archived and is no longer updated by Apple.
Apple IIGS system software after version 4.x requires at least 512K of RAM. Without at least this much you'll be limited to version 3.x or earlier of system software.

We strongly suggest that you upgrade to at least 512K of memory, even if you're only going to use the earlier system software.

ImageWriter LQ: Resetting ASCII Escape Codes

I'm using an ImageWriter LQ with a Macintosh IIsi. I want to reset the ImageWriter LQ to print 8 1/2-inch pages at 10 cpi character setting.

My document is from a program called Pacershare on a DEC VAX. I thought I had inserted the correct ASCII escape codes (from the ImageWriter LQ owner's manual) as the first commands in the document. The ImageWriter LQ does not respond to these codes, and prints only in the default 12 cpi, 11-inch page length. Any suggestions?

This article has been archived and is no longer updated by Apple.
All escape codes are overruled by the ImageWriter LQ driver. Your desired page description must be set up in the application program's Page Setup.

Published Date: Feb 18, 2012

LaserWriter: Be Sure To Use Labels Rated for Laser Printing

I'm using a LaserWriter II to print 50 sheets of standard Avery labels at a time. I'm concerned that so many labels will begin to stick to the printer's drum. Avery, the label manufacturer, claims there will be no problems. Are there any problems printing this quantity of labels on a LaserWriter?

This article has been archived and is no longer updated by Apple.
If the labels are rated for use in Laser printers or copiers, there shouldn't be problems with that quantity. We strongly suggest that you use manual feed input and the face-up output tray.

Macintosh LC: Maximum Video Depth

What is the maximum video depth the Macintosh LC's built-in video supports?

This article has been archived and is no longer updated by Apple.
The Macintosh LC's built-in video supports a maximum video depth determined by two variables:

- The size of the monitor connected to the Macintosh LC, and

- The amount of video RAM installed in the Macintosh LC.

If the Macintosh LC has 256K of video RAM installed, then the bit depth for the Macintosh 12-inch RGB display will be 8 bits per pixel, and for the 13-inch High Resolution RGB Monitor, the depth will be 4 bits per pixel.

If the Macintosh LC has 512K of video RAM installed, then the bit depth for the Macintosh 12-inch RGB display will be 16 bits per pixel, and for the 13-inch High Resolution RGB Monitor, the depth will be 8 bits per pixel.

Four bits per pixel will give you 16 colors or shades of gray on the screen at one time. Eight bits will give you 256 colors or shades of gray. Sixteen bits will give you thousands of colors.

It's possible to achieve 24 bits per pixel on the Macintosh LC through third-party Macintosh LC PDS video cards.

Macintosh LC: Using with Third-Party Color Monitors

Article Change History

10/28/92 - REVIEWED
* For technical accuracy.

I want to get more than the 256 colors on a Macintosh LC. Will the optional 512K VRAM SIMM that provides 32,000 colors on an Apple 12-inch RGB monitor be any benefit to a third-party monitor?

Is it true that a third-party monitor won't be "plug and play" on a Macintosh LC without an additional video card?

This article has been archived and is no longer updated by Apple.
Yes, the expansion option will benefit other monitors. The amount of pixel depth will depend on the size of the monitor. For a 12-inch monitor, there will be 32,000 colors; a 13-inch monitor will have 256 colors.

Third-party compatibility depends on the monitor. If the monitor matches scan rates and resolution, it should work. Ask the manufacturer for compatibility information.

Macintosh LC: Expansion Board Not Necessary for RAM Upgrade

My Macintosh LC Owner's Manual says that the Macintosh LC comes with 2MB of RAM on the motherboard that can be upgraded by adding another board AND THEN adding SIMMs to this additional board.

It certainly looks like I can put two or more 1MB SIMMs right onto what looks like two SIMM slots on the system board. To the left of these slots is a big chip. Is that the 2MB of RAM is this a ROM chip? If it's a ROM chip, are those four little chips to the left of that the RAM?

This article has been archived and is no longer updated by Apple.
The Macintosh LC doesn't need a memory expansion card. If the manual states that, it is incorrect. Simply adding two SIMMs will upgrade the memory.

Macintosh LC RAM is on four chips on the other side of the ROM SIMM socket. These RAM chips are labeled "DRAM".

To see the possible memory chips and configurations for the LC, search under "DRAM Specifications".

Macintosh IIsi: Has No Video Convolution Filter

Does the Macintosh IIsi built-in video provide a convolution filter like the Macintosh Display Card 8*24 GC does?

This article has been archived and is no longer updated by Apple.
Only the Macintosh Display Card 8*24 GC and the Macintosh Quadra computers provide a convolution filter for the video signal. It is not available on any other product.

A convolution filter is used to stabilize flicker rate on monitors.

Published Date: Feb 18, 2012

Macintosh Plus, SE, Classic: 1MB SIMMs Only

I know that System 7 allows a Macintosh II-class system or a Macintosh SE/30 to access more than 8MB of physical DRAM, and the use of higher-density SIMMs. Is the same true for the Macintosh Plus and Macintosh SE? Can I now put in four 4MB SIMMs and have 16MB of RAM in my Macintosh Plus, Macintosh SE, or Macintosh Classic?

This article has been archived and is no longer updated by Apple.

Neither the microprocessor nor the system software determines the type of SIMMs the system can use. This depends on the electrical design and the Memory Manager. The Macintosh Plus, Macintosh Classic, and Macintosh SE have address lines that support only 1MB SIMMs.

Published Date: Feb 18, 2012

TA46863_Macintosh_II_Family_Monitor_Noise_at_Startup_is_Normal_(TIL08434).pdf

Macintosh II Family: Monitor Noise at Startup is Normal

Many Macintosh II monitors make a loud noise when powering up. The high-resolution monochrome and color models seem to make this noise consistently. Is there a problem with these monitors, or is this just a characteristic of the monitor?

This article has been archived and is no longer updated by Apple.
The sound that you hear is the degausing coil being activated on power-up. Color monitors are subject to impurities from other magnetic fields. This is countered by putting a neutralizing field around the front of the CRT on power-up or by pressing the degausing coil button on the back of the monitor.

The sound is simply the coil energizing and is in no way a sign of current or future problems.

Apple High Resolution RGB Monitor: Technical Q&A

I have some technical questions about the Apple 13-inch High-Resolution RGB monitor:

1) What is the pixel size?

2) What's the pixel interleave?

3) How much time does it take to turn pixels on and off?

4) What's the wavelength range from blue to red?

5) What's the maximum brightness of the screen?

6) Can the Macintosh hardware handle programming to command video cards to display objects on the desktop (circles, squares, and so on, with different colors?)

This article has been archived and is no longer updated by Apple.

1) Pixel size (also known as "dot pitch" or "grill pitch") is 0.25mm.

2) There are no specifications on pixel interleave. If the request is for the sequence of placing pixels on the screen, then the following discussion should assist in understanding how the monitor works.

Video cards that drive the AppleColor High Resolution RGB Monitor use an approximation of the RS343 display signal. (RS video standards are set by the Electronic Industries Association.) The RS343 display standard is essentially a monochrome video signal combined with a composite sync signal (horizontal and vertical scan control) with timings that produce a non-interlace, or progressive, scan. This means that the horizontal and vertical scan rates are timed to cause the display electron guns to produce even progressively horizontal scans. This is by comparison to the interlaced video standards. The importance of the RS343 standard is its provision for a timing and voltage level signal that allows the display and generation of high resolution video.

While the Macintosh II version of the RS343 signal varies somewhat, it essentially follows the guidelines necessary for connection to RS343 display devices. The major differences are:

- the separate TTL level composite sync signal found on pin 3
- the separate video lines used to produce RGB color
- a vertical scan rate of 66.67Hz to reduce screen flicker
- a voltage white level of 1 volt for its red and blue signals and 1.3 volts on its green signal

RS343 provides for a 60hz signal but has been changed to 66.67Hz on the Macintosh II Video Card, to prevent the screen flicker visible at 60Hz.

3) The pixel clock frequency is 30.24 MHz. The only other specification that would appear to relate to this issue is phosphor persistence, which is rated by phosphor vendors as medium-short.

4) Due to contractual agreements, this information is not available.

5) Luminance level is 20 footlamberts with the brightness control in the center detent position. With the brightness control in the full-open position, the luminance level is 25 footlamberts.

6) The Macintosh firmware (the Macintosh Toolbox) has QuickDraw routines to handle the creation of the desired objects. Typically, the video cards are not "commanded" to display objects. Video cards will display the information that is placed in the video buffer. QuickDraw is used to place the information in that video buffer. The only possible exception is when a graphics coprocessor card is placed in the Macintosh. However, the Macintosh interface to these specialized video cards is still through QuickDraw. Although, now QuickDraw is being executed by the graphics coprocessor, not by the system's primary CPU.

Apple IIe: Stopping the blink of the cursor

This article discusses how to stop the blinking cursor on the Apple IIe.
This article has been archived and is no longer updated by Apple.
There are two ways to stop the blinking cursor on the IIe.

1. If you have an 80-column card, do a PR#3 and then an ESC 4. This uses the 80-column firmware but in 40-column mode.

2. If there is no 80-column card installed on your system, do a POKE 49162,0:PRINT CHR$(4)"PR#3". This has the same effect.

In the 80-column firmware, the cursor is an inverse blank. This effectively removes the flashing cursor.

PostScript: How To Create PostScript Text Files

I want to output PostScript files from my Macintosh to a VAX. I plan to use a conversion utility to interpret the PostScript file and translate it into SIXEL graphic data for output to a laser printer.

How do I get the Macintosh to create this PostScript text file?

This article has been archived and is no longer updated by Apple.
Here's how to print a PostScript image "to disk" rather than to a printer:

First, use the Chooser to select a LaserWriter. Then, choose Print... from the File menu.

Under System 7, click "PostScript File" instead of "Printer" in the Destination option of the Print dialog, and click Okay.

Under System 6, click Okay, then immediately hold down the Command key and press either:

* The "K" key (to dump a PostScript image with LaserPrep), or

* The "F" key (to dump PostScript without LaserPrep).

Hold the keys down until you see the Print Status dialog box.

A text file will appear containing the PostScript text.

Apple IIGS: How To Print from BASIC or Pascal over AppleTalk

Using an Apple IIGS, how do I print from Applesoft BASIC or Pascal to an AppleTalk ImageWriter or to a LaserWriter running ImageWriter emulation?

This article has been archived and is no longer updated by Apple.
It is similar to printing through a serial connection, except that Chooser II has to be on the boot disk the first time and a printer must be chosen.

1) Boot from disk with chooser II

2) Run Chooser and select Printer.

3) To print from BASIC, use PR#1 on a new 1MB Apple IIGS; use PR#7 on an older Apple IIGS.

Published Date: Feb 18, 2012

ProDOS: Converting Files from 5.25-inch Disks to Macintosh

I'm trying to transfer files from 5.25-inch ProDOS disk to Macintosh SE 3.5-inch disks using a 5.25 drive with a Macintosh SE Bus Controller Card.

This works fine with IBM disks, but AFE won't read ProDOS disks (or even give me the option select to select a ProDOS driver).
This article has been archived and is no longer updated by Apple.
The Apple PC 5.25 Drive for the Macintosh SE can see MS-DOS files, but not ProDOS files.

Use the utilities on the Apple II to do a file copy from a 5.25-inch to 3.5-inch, then open the file in the Macintosh SE and convert it using Apple File Exchange with your Apple SuperDrive (formerly Apple FDHD).

LaserWriter IISC: Can‘t Have Two Computers Using Its SCSI Ports

Can I connect two Macintosh computers to the two SCSI ports on a LaserWriter IISC? Can I hook up any SCSI device to these ports (scanners, hard drives)?

This article has been archived and is no longer updated by Apple.
Having two Macintosh computers connected via the SCSI port to one LaserWriter isn't an Apple-supported configuration. If something gets damaged as a result of a connection like this, it will void your warranty.

You can connect other peripheral SCSI devices, such as hard drives or scanners, but not other computers.

Published Date: Feb 18, 2012

AppleShare: Dealing With "No Valid Startup Volume Found" Message

I've been using a Macintosh AppleShare File Server for about six months with no problems. Suddenly, when it was restarted after a power failure, I got a message that I needed to run AppleShare Admin again.

I ran the Admin program, then after restart, I got the error message "No valid startup volume found".

This article has been archived and is no longer updated by Apple.
Here are the steps you should take:

1) Do a file-by-file backup of your volume. Keep in mind that a file-by-file backup will not retain access privileges, so you'll have to recreate them if you need to restore from this backup.

2) Since the volume is not available to the application, you will have to re-prepare the volume for use with AppleShare and recreate the parallel directory structure (PDS). You will lose access privileges doing this -- but you'll lose no data. This should get you back to a functioning server.

3) If the problem persists, reinitialize your volume, prepare for use with AppleShare, and restore all your files from the backup you did before starting.

Macintosh: Troubleshooting "Non-Apple Disk Error"

My Macintosh keeps giving me a "Non-Apple Disk Error" when I insert a floppy disk, and asks me if I want to reformat the disk.

This article has been archived and is no longer updated by Apple.
If it occurs only with one or two diskettes, there may be a problem with those disks and not the drive. If this problem only occurs when using disks of a certain brand or density, consider trying another brand of diskette. If a given diskette produces the same error in another computer, then almost certainly the problem is with that disk.

However, if this happens no matter what disk you insert - even master application disks - the problem most likely is with the disk drive itself.

Published Date: Feb 18, 2012

Macintosh: Using IBM SCSI Drives

Is there a difference between Apple SCSI and everyone else's SCSI? What are the differences between IBM SCSI and Apple SCSI, particularly with hard drives? Can I use an IBM 20MB SCSI hard drive in a Macintosh? Any warranty problems (would it void your warranty or AppleCare)?

This article has been archived and is no longer updated by Apple.

If you swap just the hard drive mechanism, it should work. The controller will be different--the ROM in particular.

There really isn't an Apple SCSI vs. Standard SCSI. ANSI determines the SCSI standards, and Apple provides input to the standard. The problem is that SCSI is an evolving standard.

ANSI is the American National Standards Institution

This would not be an approved repair for an Apple Warranty or AppleCare.

Macintosh: Changing Font Size in Menu Bars

This article has been archived and is no longer updated by Apple.

At the end of this article is the MPW Assembly source code for an Init file that, when placed in the System Folder, modifies three low memory globals at startup.

The Init changes the System font from Chicago 12 to Chicago 14, the largest font that doesn't cause distortion in dialogs and buttons. (You must, of course, have Chicago 14 installed in the System file.) Menu bars and window title bars will change in size based on the values you supply.

Warnings: This method of changing the size of the system font is not recommended, but is the easiest way to change the font size of the menu bar with existing System files. The Init has been tested with few applications, but may not work with all programs. It makes direct calls to hardware locations and may not work with future versions of hardware or of system software.

For more information, see:
- the Font Manager Chapter of Inside Macintosh, volume III
- the Menu Manger Chapter of Inside Macintosh, volume V

Here is the source code for the ChangeFont Init:

Ultrasonic Humidifiers and Computer Equipment

The inside of my computer is coated by something other than dust. The only source of contamination seems to be my cool mist humidifier.

Is there any information regarding ultrasonic humidifiers and their effects when placed close to computers? Specifically, can the mineral mist be attracted to the electrical components inside a Macintosh or LaserWriter?
This article has been archived and is no longer updated by Apple.
Dust in general is not good for computers: it causes heat build up and gets between the various connectors, particularly the SIMMs which can cause errors or other operational problems.

An ultrasonic humidifier should not cause any more damage than common dust.

Apple Monitors: Nearby Interference can Cause Horizontal Lines

A horizontal scan line keeps cycling down my computer screen. How can I correct this?
This article has been archived and is no longer updated by Apple.
The line you are seeing is caused by a 60 Hz noise somewhere near the monitor. When the horizontal scan rate of the monitor is 60.15Hz, it is very susceptible to external noise in the 60Hz area. The only solution is to find the source of the noise and move it or move the monitor. The noise could be from a lamp or anything else plugged into a nearby outlet.

You may also want to try turning the monitor in different directions to see if things improve at all. The interference may change due to magnetic fields.

Macintosh: Daisy-Chaining 3.5-Inch Floppy Drives Not Supported

Can I daisy-chain two or more 3.5-inch drives on a Macintosh?

This article has been archived and is no longer updated by Apple.
You can't daisy-chain floppy drives with any Macintosh computer.
Daisy-chaining works only on the Apple II product line.

Published Date: Feb 18, 2012

Display Card 8■24 GC: Problems with PC 5.25 Drive Card (11/94)

I've been having problems with my Macintosh Display Card 8*24 GC with a PC 5.25 Drive card. I removed the Apple PC 5.25-inch Drive card from my Macintosh, re-accelerated the Macintosh Display Card 8*24 GC, and everything works fine.

This article has been archived and is no longer updated by Apple.
The Apple PC 5.25 Drive sometimes clashes with the NuBus clock. This happens because the card has a 13-inch trace and six leads on that line. Symptoms of this issue include other installed NuBus cards not functioning properly. For example, NuBus video cards do not appear installed, and networking cards do not provide access to a network.

Putting the card in slot $E helps minimize the problem. If you experience a problem, try running with the PC 5.25 Drive card in slot $E.

Apple IIe Card: Macintosh Compatibility

Which Macintosh computers are compatible with the Apple IIe Card?
This article has been archived and is no longer updated by Apple.
The Apple IIe card is only compatible with computers that have the LC style processor direct slot (PDS) and do not require 32-bit addressing. This includes:

- Macintosh Color Classic
- Performa 400 series
- Macintosh LC/Performa 500 series computers (except the Macintosh LC 580 and Performa 580)
- Macintosh LC series computers except: Macintosh 630 family, Power Macintosh 5200 and 5300 LC, Macintosh Performa 5200, 5300, 6200, 6300 series.

The Macintosh LC 580, Macintosh 630 Family, Power Macintosh 5200 and 5300 LC, Performa 5200/5300 and 6200/6300 series only operate in 32-bit addressing mode. Since the Apple IIe card is not compatible with 32-bit addressing, the Apple IIe Card is not compatible with these computers.

The Power Macintosh 5400 and 6400 series and the Macintosh Performa 6400 series and 6360/160 computers do not have LC-PDS slots. These computers have PCI expansion slots. Thus, they do not support the Apple IIe card.

Compatibility Table

TA46888_Apple_II_FORTRAN_Double_precision_arithmetic_(TIL00846).pdf

Apple II FORTRAN: Double precision arithmetic

Usually, in FORTRAN IV & 77, the way to handle numbers up to 10 to 11 significant figures is to declare double precision variables or implicit double precision variables.
This article has been archived and is no longer updated by Apple.
The new strategy here is to use the Pascal SANE unit linked to a FORTRAN program following the instructions in the Apple FORTRAN Language Reference Manual Chapters 15 and 16. Double precision poses more difficult problems.

With the advent of the SANE package there are solutions possible. In short, such Pascal units are not available and must be written and created by the FORTRAN user.

TA46889_Macintosh_Classic_Power_Size_Requirements_for_Internal_Drives_(TIL08465).pdf

Macintosh Classic: Power & Size Requirements for Internal Drives

What are the limitations regarding the Macintosh Classic and third-party internal hard drives, specifically power consumption and physical size?

This article has been archived and is no longer updated by Apple.
An internal hard drive for the Macintosh Classic drive must not be more than "1/3 height" (meaning one inch) in height. There simply isn't any room for larger hard drive.

The exact power figure for the Macintosh Classic's drive connector is 10 watts, but power consumption isn't an issue for most 1/3 height drives.

Laser Prep: Must Be In Sync With LaserWriter Driver

I'm having problems with printing from my Macintosh since upgrading my Laser Prep file. I keep getting "Print Monitor unexpectedly quit" errors and lock-ups.

This article has been archived and is no longer updated by Apple.
There is no upgrade of just the Laser Prep file. LaserWriter and Laser Prep must be upgraded together. For example, you need to use LaserWriter 5.2 with Laser Prep 5.2 or LaserWriter 6.0 with Laser Prep 6.0.

Note however that Laser Prep is no longer required as of version 7.0 of the LaserWriter driver. The System 7 version of the driver sends the prep information along with each print job. Any Laser Prep files that for some reason remain in the System Folder will not cause any damage, but also will not help printing. They can be trashed.

Macintosh II Family: Improving Sound Sampling Rate

I want to get better sound quality out of my Macintosh IIsi. I've read that the Macintosh IIsi can sample sound at 11kHz and 22kHz. How can I change my sampling rate to 22kHz? Can I also upgrade my sound chip from 8-bit to 12-bit?

This article has been archived and is no longer updated by Apple.
The sampling rate for the Macintosh IIsi is set at 11khz by the software that comes with the Macintosh IIsi. Third parties will be delivering software that will take advantage of the greater sound capabilities of the Macintosh IIsi in the near future.

There's no way for you to upgrade the Macintosh IIsi sound chip as it is soldered to the logic board. Any upgrade has to be done by Apple at the factory.

In terms of hearing a better output, you hook up your Macintosh to a stereo system, or simply attach some speakers to the Sound Port on the back of the Macintosh. Bose is one company that makes speakers that are popular with the Macintosh.

Third-Party Hard Drives: Changing Their Desktop Icons

Even though I've completely reformatted my third-party hard drive, the drive keeps appearing on my desktop with the third-party's icon. How can I do a low-level drive format to remove their icon?

This article has been archived and is no longer updated by Apple.
Apple does not supply a low-level formatting utility with any of our system software. This level of formatting is handled by the third-party vendor before they ship their drives. Apple's drive utility software only initializes the drive.

You might want to try Silverlining from La Cie. Silverlining can give you back the generic icon. There are also some icon altering utilities.

The Tech Info Library article titled "**Locating Vendor Information**" can help you search for a particular vendor's address and phone number.

Macintosh IIfx: Problems Getting Internal Hard Drives to Start

Article Change History

11/04/92 - UPDATED
* To explain that there is a small power trace difference on the Macintosh II and Macintosh IIfx logic boards.

My internal hard drive stopped working after upgrading my Macintosh II to a Macintosh IIfx. The drive just clicks and won't spin up.

I've been told by the drive's manufacturer that this is because the power trace on the Macintosh IIfx motherboard is half the size of the same power trace on the Macintosh II. Is this correct?

This article has been archived and is no longer updated by Apple.
There is small difference in the power trace from the Macintosh II to the Macintosh IIfx. However, the difference would be within the limits of the power draw specifications that we require drive manufactures to meet.

If your particular drive is drawing more than Apple allows, you'll need to swap drives for one that does not require so much power to spin up.

AppleShare: Macintosh LC vs. Macintosh SE/30 Performance

What are the advantages and disadvantages of using the Macintosh LC as an AppleShare file server compared to a Macintosh SE/30 or Macintosh II (besides the available expansion slots in the Macintosh II)? Does AppleShare take advantage of the MC68881/MC68882 math co-processors? Are there any compatibility problems between AppleShare 2.01 and the Macintosh LC?

This article has been archived and is no longer updated by Apple.
Compared to a Macintosh SE/30, the Macintosh LC is slower. The Macintosh LC uses a 68020 chip where the Macintosh SE/30 uses the 68030 processor.

There are no known compatibility issues between AppleShare 2.0.1 and the Macintosh LC. If speed is not an issue and price is, the Macintosh LC would be a good choice for a file server.

AppleShare really doesn't utilize a math co-processor so this is not really a factor.

Macintosh: Troubleshooting Multiple Hard Drive Icons

When I start up my Macintosh, multiple icons of my hard drive mysteriously appear on my Desktop.
This article has been archived and is no longer updated by Apple.
There are several causes of this symptom, including SCSI ID conflicts, damaged system software, or corrupted PRAM.

The most common cause is having a SCSI device with a SCSI ID 7, which is the same address reserved for the computer. To resolve this, check to see if either the internal or external hard drive or other SCSI device has a SCSI ID 7. If so, change it to a unique number; all devices on the SCSI bus must have different SCSI ID numbers.

Next, try starting up from the system software CD or Disk Tools floppy disk. If you do not see multiple hard disk icons when starting up this way, then you likely need to reinstall your system software. If you still see multiple hard disk icons, use HD SC Setup or Drive Setup to update the hard disk driver.

If the multiple SCSI disk icons persist, then reset the PRAM. To do this, hold down the Command-Option-P-R keys simultaneously as you start up the computer. Do not release the keys until you hear two startup chimes.

AppleShare: Problems Using Chooser with Apple II Computers

I recently set up an AppleShare Network with Apple II and Macintosh computers. All seemed well except for a small item on the Apple II side.

Using Aristotle, everything works fine except the Chooser.

When trying to use Chooser, the window opens to show the application just short of finishing. The Chooser then stops with a message that it cannot load or open:

/System/System.Setup/ATInit

How can I repair the above file without reinstalling the entire AppleShare network?

This article has been archived and is no longer updated by Apple.
If you're using Apple IIGS computers, you don't need to use the Chooser anymore. Select printers with the Control Panel.

If you're using Apple IIe computers, be sure you use the AppleShare Apple II Setup Disk 2.1.1 or greater when setting up your server.

Published Date: Feb 18, 2012

Macintosh: Using IBM PC SIMMs

Can I use IBM SIMMs in a Macintosh II? The SIMMs are the same size as Macintosh SIMMs and are rated at 80ns. The only real difference is that they have a parity bit. Will this extra bit cause a problem or can the Macintosh just ignore the parity bit?

This article has been archived and is no longer updated by Apple.

The memory should be compatible, the parity chip will be ignored by the Macintosh. We would not expect any damage if the SIMM is incompatible, the machine just won't work.

Macintosh Finder: Reasons for Slow Operation

This article has been archived and is no longer updated by Apple.

TOPIC ----------

What could make the Finder run slowly?

DISCUSSION ----------

A slow Finder is not caused by the size of the disk, but by the size of the Desktop file. The size of the Desktop file is not directly related to the number of files it contains, but to the number of icons and file comments.

The number of icons is related to the number of applications. Slow operation becomes a problem for hard disks with more than 50 applications. The number of comments is a problem only for those who add a comment to every file and folder. This is typical with public domain software. To remove all comments, you can rebuild the Desktop file in one of two ways.

- You can delete the Desktop file in ResEdit.

- You can hold down the Command and Option keys while you start up your computer.

These operations remove the comments and speed things up appreciably.

Macintosh: Opening Documents and Differing Application Versions

When I double-click on a document, the Macintosh Finder also launches the application that created the document. However, when there is more than one copy of an application on a volume, the copy of the application that gets launched isn't predictable.

1) How does the Finder determine which application to launch?

2) Can I control which version of the application will be launched?

This problem is especially annoying when still working with HyperCard 1.2.x and 2.x.

This article has been archived and is no longer updated by Apple.
1) There are two different answers to this question, one for System 6 and one for System 7:

In System 6, a volume that has two or more copies of an application, or where there are different versions that use the same creator, the last copy installed on that volume is the one that launches.

In System 7, the application with the most recent creation date is the one that launches.

2) There is no way to change this. However, a sure way to eliminate the version confusion is to change the Creator of the applications you don't want to launch.

For example, use ResEdit to change the creator of HyperCard from "WILD" to "FRED". When you double-click on a stack, the system will go looking for the application whose creator matches the creator of the document (stack). If you have another copy of HyperCard (say, 2.0v2) on a mounted device, it will be launched. Saving files from the changed application is unaffected (they still have "WILD" for their creator).

So, your solution is to change the creator of all non-current HyperCard applications to something other than "WILD" (try "DLIW"; it's probably not used by other applications). All stacks launched will come up in HyperCard 2.0v2. Opening the stacks in other versions is done by launching the application and using "Open╔" in the file menu.

MacWrite II: Early Versions Don‘t Fully Support TrueType

Using MacWrite II version 1.1, when I create text in TrueType Times above the 127 point size, and have the strike-through feature, the strike-through line appears above the text. When I try to edit the text, the "I" beam doesn't go where I click.

Is this a problem with MacWrite or TrueType?
This article has been archived and is no longer updated by Apple.
MacWrite II 1.1v1 and earlier versions do not support TrueType when using font sizes larger than 127 point. Claris is working on a new version of MacWrite II that will solve this problem.

A/UX 2.0.1: Solution for "syschk" Error Problem

I'm having a problem with the System Checker disk of the A/UX v2.0.1 release: the shell script syschk is not executable (protection 444 instead of 555). I changed the protection to the right value and then I got an error message when running the syschk command: "Message too long".

This article has been archived and is no longer updated by Apple.

```
We have verified the problem.  The 'syschk' Korn Shell script file in the
A/UX 2.0.1 distributed System Checker disk seems to be missing some "echo"
statements before the displayed error message.  The echo statements should
be inserted before the displayed message, around lines 145 and 168 in the
syschk script file.  They should be changed to the following:

          if [-n $noopt"]; then
          echo "\\n             <================ inserted
      Error - insufficient room in / partition.
      At least $need more free blocks needed to install optional files.
      Optional file (manuals, games) disregarded in calculations.
          "                    <================ inserted

          if [-n $noopt"]; then
          echo "\\n             <================ inserted
      Error - insufficient room in /usr partition.
      At least $usrneed more free blocks needed to install optional files.
      Optional file (manuals, games) disregarded in calculations.
          "                    <================ inserted

Note: If the script was written in Korn Shell not Bourne Shell, use 'ksh
syschk' instead of 'sh syschk'.  The 'syschk' file is unnecessarily changed
to executable if it is invoked by 'ksh syschk'.  The "Message too long"
message results from the Bourne Shell.
```

A/UX Sockets and FASYNC Signal

Article Change History

08/31/92 - REVIEWED
o For technical accuracy.

I'm trying to port a BSD sockets-based application to A/UX. I'm running on Sun and DEC Ultrix platforms.

My problem is I can't find support for sending asynchronous signals via sockets. Other platforms have a flag in the file control header /usr/include/fcntl.h called "fasync". The flag is needed to send asynchronous signals.

Does Apple support this feature?

This article has been archived and is no longer updated by Apple.
We looked into the /usr/include/fcntl.h file on an Apple Campus UNIX machine (apple.com, a BSD 4.3 UNIX system), and the FASYNC flag is defined in the /usr/include/fcntl.h header file. In A/UX, instead of defining in the /usr/include/fcntl.h file, it is defined in the "/usr/include/sys/file.h" file with this statement:

#define FASYNC 0x00000040 /* signal pgrp when data ready */

Therefore, we think it is supported in A/UX because the BSD socket library is supported under A/UX.

MacTCP: Broadcast Address Ranges, Problems & Workarounds

I am running into an issue with the TCP connection tool. I'm trying to run MacX and Telnet/TCP. Both are failing. I can run Telnet that uses its own TCP/IP, so I know that the physical connection is there.

When I try to run MacX, I get the message, "none of the connection tools are working at the moment...". And with Telnet/TCP 2.3, I get the familiar flash of the screen and then it quits to the Finder. I've worked with MacX and MacTCP on several occasions, so I don't think it's an installation Error.

I have gotten this same error message when a gateway has been down. That leads me to believe that there is a configuration issue on the host/network side.

Host:
Sun 128.0.0.2
subnet FFFF0000
broadcast 128.0.0.0 had them change to 128.255.255.255

1) What are the valid IP address ranges for class A, B, and C IP nodes? Is this documented in any specific RFC?

2) Is it true that if a host TCP/IP implementation uses zeros for broadcast address bits, that:

* Can't interoperate with it and A/UX or MacTCP?

* The host must have a new implementation of TCP/IP added to make it interoperable?

3) Do you know of any "standard" written down in an RFC?
This article has been archived and is no longer updated by Apple.
MacTCP does NOT support 0's as broadcast address bits, so your systems need to be reconfigured to support 1's as broadcast bits. Changing your Sun and MacTCP values will fix the issue:

Hosts:
Sun: 128.1.1.1
subnet: 255.255.0.0
broadcast: 128.0.255.255

Macintosh: 128.1.1.4
subnet: 255.255.0.0
broadcast: 128.0.255.255

MacTCP-based application error messages often leave out the most common error possibility -- an invalid address. MacX, for example, gave the error message to check installation of the MacTCPTool, when in fact it was the IP addressing scheme itself that was wrong.

MacTCP DOES accept "INVALID" TCP/IP addresses without complaining, and will then fail to attempt any connections with those addresses. You can configure "invalid" addresses, like 128.0.0.0 or 0.0.0.255, without any complaints, but there will not be any support for application services on top of them.

1) Here are the valid IP address ranges for:

Valid Class A IP addresses: 1.0.0.1 through 127.255.255.254. In a class A IP address, the first octet contains the network number. The second, third, or fourth octet must contain a non-zero value. Examples of valid addresses include: 17.5.0.0; 45.0.0.200; and 50.0.120.0.

Valid Class B IP addresses: 128.0.0.1 through 191.255.255.254. In a class B IP address, the first and second octets contain the network number. The third or fourth octet must contain a non-zero value. Examples of valid addresses include: 135.0.17.0; 160.0.0.210; and180.22.120.0.

Valid Class C IP addresses: 192.0.0.1 through 223.255.255.254. In a class C IP address, the first, second, and third octets contain the network number. The fourth octet must contain a non-zero value. Examples of valid addresses include: 221.5.0.1; 198.0.0.200; and 202.0.120.23.

Also internet addresses in the range 128.0.rrr.rrr, and 192.0.0.rrr are
reserved. MacTCP doesn't allow use of this address, and issues a "bac
ip or LAP configuration error".

2) MacTCP, under the Macintosh OS, uses 255 for broadcasts, not zero. In other words, a broadcast on a class network would use an address like this: 17.255.255.255, not 17.0.0.0. A/UX, or MacTCP running under A/UX, can be configured to use zero for broadcasts (for example 17.0.0.0).

You cannot use MacTCP, under the Macintosh OS, on a network that does not use 255 for broadcasts.

3) RFC 1166 is the document with the information you need.

A/UX 2.0.1: Problem Recognizing 800K Drives with Macintosh IIfx

I am using A/UX on a Macintosh II that has been upgraded to a Macintosh IIfx.

A/UX seems to think my 800K floppy drive is a 400K drive and that it is bad. In fact, we can format floppies to 800K and otherwise use the drive. But the A/UX Finder and DOSMounter certainly believe that the drive is 400K and will only format it or use it as 400K.

An Apple Macintosh IIfx with an FDHD and an 800K drive, booting under A/UX release 2.0.1 version SVR2 has the following symptoms:

* The 800K floppy drive is only recognized as a 400K drive.

* Part of the message from the A/UX kernel during boot reads "FD:floppy driver ver. 1.9; iop swim, D1 is 400K (1 head), D0 is an FDHD drive." "FD: D1 400K drive unusable."

* If the unit is not booting under A/UX, the 800K drive operates as expected.

This article has been archived and is no longer updated by Apple.

It is a floppy driver incompatibility in A/UX 2.0.1 with a Macintosh IIfx. On a Macintosh IIfx, the driver incorrectly identifies the drive as a 400K drive, and claims it's unusable because 400K drive hardware isn't supported on the Macintosh II series systems. If you insert a blank floppy, however, you can format it, but only as 400K single-sided floppy. The drive is still usable as a 400K drive.

You can still read and write existing 800K floppies, even though the drive says you can't.

This problem has been fixed with A/UX 3.0 and above.

Color Picker: Relationship of Values to RGB Gun Voltages

Is there any relationship between the 65535 values (for example, of the Color Picker) and the analog voltages of RGB guns in color monitors?

This article has been archived and is no longer updated by Apple.

There isn't a direct relationship between the two, but there is a proportional relationship.

A zero setting of the Color Picker's red field causes minimum volts at the red gun of the monitor. The 65535 setting of the Color Picker's red field gives maximum voltage at the red gun. The same is true of the blue gun and the green gun.

No two monitors have the same voltage settings, because of differences in the gamma tables, the analog adjustments of the monitor, and the monitor's voltage specifications.

(The following STARTDISCUSSguns in the color monitor.)

To get the exact voltage relationship to Color Picker values requires selecting the uncorrected gamma table in the Monitors CDEV.

1) Hold down the option key while selecting the option button in the CDEV.

2) Once the uncorrected gamma table is in use, set each of the red, blue, and green values of the Color Picker to 0 (zero). Measure the voltage of the guns. This will be the minimum voltage of the guns.

3) Set each value of the red, blue, and green Color Picker fields to 65535. Now measure the voltage of the guns. This will be the maximum voltage produced by the guns.

As long as the uncorrected gamma table is in use, there should be a linear relationship between the Color Picker values and the gun voltages.

However, the analog adjustments of the monitor can affect the linear nature of this relationship. Also, if a corrected gamma table is selected, the linear relationship is further perturbed.

System 7: Sharing CD-ROM Discs & Other Removable Media

When I try to disconnect (unmount) a CD-ROM on my Macintosh running System 7, I get a message stating that the CD-ROM volume cannot be unmounted because it is being shared. However, File Sharing status shows no volumes or folders being shared. Depending on the type of Macintosh being used, restarting the Macintosh may or may not correct the problem.
This article has been archived and is no longer updated by Apple.
When File Sharing starts up, it takes a snapshot of the volumes available on the current desktop. All volumes (excluding floppies, which cannot be shared) are "implicitly" shared. This occurs even if no one is connected to your system, and you have not explicitly shared any folders or volumes via the Sharing menu.

If a CD-ROM isn't inserted into the drive when you start File Sharing, you can't share the CD-ROM. Also, if you turn on File Sharing while a CD-ROM is inserted into the drive, you can't eject the CD-ROM.

When you start File Sharing, you make all volumes on your system available to the owner from anywhere on the network. Therefore, your CD-ROM (or audio CD), and any other removable media, such as removable hard drives and optical drives, are now being shared for the owner and can't be removed.

If you make a volume available to your system after File Sharing has been started, that volume won't be available to the owner unless you explicitly share it via the Sharing menu. Therefore, once you start File Sharing either by starting up with it active, or through the Sharing Setup Control Panel, you can mount and unmount new volumes as often as you like until they are explicitly shared.

To unmount (remove from your desktop) a volume that has been implicitly shared:

1. Turn File Sharing off.
2. Remove the volume.
3. Turn File Sharing back on without restarting your system.

Note: as of System 7.5, Update 1.0, file sharing was modified to allow removeable media to be shared/unshared without having to turn file sharing on and off

On most Macintosh systems, restarting works because the CD-ROM is ejected at restart, File Sharing is reset, and then you re-insert the CD-ROM. However, on other systems such as a Power Macintosh with the CD 300i Plus drive, restarting will not work because it does not eject CD's on restart.

You can share an Audio CD-ROM, but you can't use the CD Remote DA to control someone else's CD-ROM. This means an Audio CD-ROM has the same problems that removable media does with System 7 File Sharing. If you turn File Sharing on with an audio CD-ROM in the computer, it's shared. You must turn off File Sharing to eject the volume. To avoid this problem insert the audio CD-ROM after File Sharing is already turned on.

System 7: Virtual Memory and Largest Unused Block

My Macintosh has 4MB of RAM, and I set it to 24-bit addressing mode with 13MB of virtual memory. I see the following distribution of RAM according to "About This Macintosh."

Built-in memory 4,096K
Total memory 13,312K
System Software 1,577K
Largest Unused Block 7,319K

System Software added to Largest Unused Block equals 8,896K. This leaves 4,416K missing.

When I set the Macintosh to 32-bit mode, I see the following distribution of RAM:

Built-in memory 4,096K
Total memory 13,312K
System Software 1,577K
Largest Unused Block 11,712K

System Software plus Largest Unused Block equals 13,289K.

Why does there appear to be more memory available with 32-bit addressing turned on?
This article has been archived and is no longer updated by Apple.
Virtual memory in 24-bit addressing mode fragments the memory available when you set the memory size to greater than 8MB. Virtual memory in 32-bit addressing doesn't face this limitation. The following examples show how this happens.

24-Bit Addressing
Setting your Macintosh to 24-bit addressing mode makes 16MB available to the computer. Here's what the memory map looks like in 24-bit mode:

MB	Function
1-8	Physical & Virtual RAM
9	ROM
10-15	NuBus slots
16	I/O

When you set virtual memory greater than 8MB, the location of ROM in the memory map fragments the free memory. So the largest block available will always be 8MB minus memory any running applications use, until you exceed 8MB. After exceeding 8MB, the largest available blocks are the memory mapped into NuBus slot space.

The memory available to applications (application heap) includes the first 8 megabytes, plus any memory the NuBus cards (10-15) aren't using that has been mapped as memory by virtual memory. This is where the RAM available under virtual memory becomes fragmented. In the example of RAM distribution for 24-bit addressing, 11,735K of RAM is really available for the application heap even though the Largest Unused Block shows as only 7,319K.

32-Bit Addressing
Setting the Macintosh to 32-bit mode prevents fragmenting available memory because it maps ROM and I/O to the top of the memory map. This makes 1GB available to the computer. Here's what the memory map looks like in 32-bit mode:

Memory	Function
1GB	Physical & Virtual RAM
256MB	ROM
2.5GB	NuBus slots
256MB	I/O

Virtual memory in 32-bit mode only accesses the 1GB RAM memory space. This leaves the memory space between system heap and ROM available. The application heap is a contiguous block in the top thousand megabytes of the memory map. In the example for 32-bit addressing, the Largest Unused Block (11,712K) is equal to the total RAM available for the application heap.

HyperCard 1.2.5: System 6.0.7 Workaround for Sound Issues

I've read somewhere that HyperCard 1.2.5 doesn't run properly under System 6.0.7, especially when sound is involved.

System 6.0.7 is required for a Macintosh LC, so how can one resolve this issue without going to HyperCard 2.0 for the time being?
This article has been archived and is no longer updated by Apple.
HyperCard 1.2.5 is not fully compatible with System 6.0.7. If you never "play" a sound, it works fine, but because Apple can't guarantee that sounds will never be played, the software is listed as "incompatible".

Claris suggests turning the volume all the way down; in effect, turning the sound off.

Here's another workaround for turning the sound down: add the following two handlers to Home's stack script:

```
on play
--stops most play commands getting through to HyperCard, it's unlikely
--that a stack would have used "send play ... to HyperCard".
end play

on beep -- flash the menu bar instead of beeping
type space with commandkey
type space with commandkey
end beep
```

PostScript: Displaying Output on Macintosh Screen

I want to create a PowerPoint presentation using a "screen shot" from a VAX workstation. I have made a PostScript file on the VAX that I downloaded to my Macintosh as a text file. On my Macintosh, the file shows up as a series of PostScript commands, as opposed to an image that the Macintosh can display properly.

Other than Display PostScript, do you know of any way to read in a PostScript file and have it displayed on-screen as it would appear on the printer? Is there a utility that would 'interpret' the PostScript file into a QuickDraw-generated screen display?

This article has been archived and is no longer updated by Apple.
It is possible to display an EPS (Encapsulated PostScript) file with many Macintosh applications, including Adobe Illustrator.

To display full PostScript files under the Macintosh OS, use an application like LaserTalk from Emerald City Software or PostShow from Lincoln & Co.

It's possible that your PostScript files generated on the VAX wouldn't be well-behaved enough to work with PostShow. Extremely complex images can have problems. It also may not be worth it to buy this product for a one-time need. Many users duplicate the displays of non-Macintosh computers by hiring an artist to draw it using a Macintosh graphics program. The decision is usually based on how many times the conversion will be required.

Search on company names for contact information.

TA46951_LaserWriter_II_Intelligent_Controller_Box_(TIL08536).pdf

LaserWriter II: Intelligent Controller Box

Is there an intelligent controller box for a LaserWriter II that allows both AppleTalk and serial communications without resetting the printer?

This article has been archived and is no longer updated by Apple.
BridgePort, from Extended Systems, allows input from RS-232, parallel, and LocalTalk sources. Unfortunately, BridgePort only outputs via parallel or RS-232. This works with a LaserWriter, but does not take advantage of the LocalTalk port. You can use it with non-Apple PostScript printers that don't have a LocalTalk interface.

Macintosh IIfx: Problems Using with UB MaxTalk

I am using Ungermann-Bass Access/One to connect Macintosh computers via the LocalTalk port to the UB MaxTalk card. Everything works fine with all Macintosh models except the Macintosh IIfx. The connection is weak or very slow.

I've installed the Serial Switch CDEV, and that solves the problem. My Macintosh computers are using only AppleShare Workstation software and System Software 6.0.7 to connect to the AppleShare server.

Some questions:

1) Have you heard of problems with the Macintosh IIfx and the UB MaxTalk Card?

2) Can you give me more details on the Serial Switch CDEV?

3) Is this an Apple problem or because the Ungermann-Bass product doesn't follow AppleTalk guidelines?

This article has been archived and is no longer updated by Apple.
1) Ungermann-Bass Tech Support confirms the problem. They also state that using the Serial Switch CDEV solves the problem.

2) The Serial Switch CDEV for the Macintosh IIfx lets you bypass the IOP for the SCC chip, enabling compatibility with serial devices that don't work with the IOP. The I/O Processor (IOP) is an Apple custom IC designed to provide intelligent support for I/O controllers. There are two of these IOP chips in the Macintosh IIfx computer: one for the SWIM and ADB and one for the SCC. The IOP sits between the main processor and the I/O controllers.

The features of the IOP include:

* A built-in microprocessor (6502 running at 2 MHz)

* A 17-bit timer

* Two DMA controllers: one for each serial I/O channel (only used in the Serial IOP)

* Address and data buses for RAM used by the IOP and host processor

* Two digital I/O ports for controlling the ADB (on the SWIM-ADB IOP)

* 32K of external memory of IOP code and data storage

The 68030 communicates with the IOP through a set of control registers in the IOP that are mapped into the main processor's I/O space. The main processor can interrupt the IOP using a bit in one of the control registers, whereas the IOP can interrupt the 68030 by using an interrupt line.

Each IOP has 32K of external RAM that holds the driver and acts as a buffer for the data processed by the processor. The IOP contains a 16-bit auto-incrementing address register and an 8-bit data port that the host processor uses for access to the shared RAM.

3) It's not AppleTalk guidelines that need to be followed, but serial

port guidelines. The reason Apple put an SCC IOP in the Macintosh IIfx was to handle the interaction with both serial ports. The SCC IOP handles LocalTalk to relieve the CPU from interrupts created by the LocalTalk transmission. Unfortunately, many applications accesses the SCC chips directly instead of the serial driver. Therefore, the Serial Switch CDEV was distributed for those applications to bypass the IOP.

We're not sure what the UB software does exactly and could not get the information from UB, but it is likely that they might be accessing SCC directly.

To locate a vendor's address and phone numbers, use the vendor name as a search string.

Apple 300/1200 Modem:Using one from within BASIC on an Apple II

This article has been archived and is no longer updated by Apple.
On page 3 of the Modem 300/1200 User's Manual, "Part II: Guide to Apple II", you're told to set SW2-2 on the Super Serial Card (SSC) to the OFF position. This isn't entirely correct.

Setting the switches this way causes the SSC to send data in 7 data bits and 1 stop bit, whereas Apple modems are only equipped to handle data in 8 data bits and 1 stop bit. This situation causes no problems if you're using Access II or AppleTerm. These terminal programs override the switch settings on the SSC, and send data to the modem in 8 data b; and 1 stop bit no matter what the switches on the SSC are set to.

It DOES cause problems, though, if you're using BASIC with your modem, since BASIC has no such override capability. When you use BASIC with your Apple modem, the switches on the Super Serial Card must be:

SW2-1 ON
SW2-2 ON

X Window System for A/UX 2.1: Xt and Athena Widget Set

Article Change History

08/31/92 - REVIEWED
* For technical accuracy.

X Window System for A/UX 2.1 supports Xlib and the X Toolkit. Is the X Toolkit the same as the Xt toolkit? Does the X Toolkit include the MIT Athena Widget set? What makes up the MIT Athena Widget set, and what is its relationship to X Toolkit?

This article has been archived and is no longer updated by Apple.
The X Toolkit in X Window System 2.1 for A/UX is the standard toolkit from MIT known as the X Toolkit. The Xt is short for X Toolkit.

In order to better understand the components of X, here is a summary of each component:

- Xlib (/usr/lib/libX11.a)
The standard C language library interface to X, which defines an extensive set of functions that provides complete access and control over the display, windows, and input devices such as mouse and keyboard.

- X Toolkit (/usr/lib/libXt.a)
The high-level toolkits designed for use with X to build applications easily.

The X Toolkit consists of two parts:

* The Xt Intrinsics
Xt Intrinsics supports many different widget sets. Yes, X Window System 2.1 for A/UX supports the Athena Widget Set from MIT.

* The X Widgets set
The X Widgets set implements user interface components which include scroll bars, menu, and buttons. The Xt Intrinsics provides a framework that allows the programmer to combine these components to produce a complete user interface. The entire MIT Athena Widgets Set for X Window System 2.1 for A/UX has been built and kept in the /usr/lib/libXaw.a library. You can see all modules (Box, Form, Scrollbar, and so on) of the Widget set from the output of "ar-tv /usr/lib/libXaw.a".

Both the Xt Intrinsics and the X Widgets set are written in C and built on top of Xlib. In short, the X Toolkit includes a layer known as the Xt Intrinsics which defines an architecture for combining user interface components known as widgets to create an application user interface.

TA46958_AUX_Uses_bit_Character_Set_for_Filenames_(TIL08543).pdf

A/UX: Uses 7-bit Character Set for Filenames

Article Change History

08/31/92 - REVIEWED
* For technical accuracy.

Does A/UX 2.0.1 support an 8-bit or a 7-bit character set? I would have guessed 8-bit, but I've not been able to use special characters in filenames.

This article has been archived and is no longer updated by Apple.
ASCII is a 7-bit character set code with values ranging from 0 to 127. Binary data uses the 8-bit character set, with code values ranging from 0 to 255.

A/UX supports 8-bit binary files, which are usually executable applications and binary data files. A/UX 2.0.1 recognizes only 7-bit filenames, which means you can't create filenames with character values greater than 127. Special characters prohibited by 7-bit ASCII include '/', '|', and so on.

However, Macintosh HFS filenames can use the 8-bit character set.

System 7: Compatibility Checker 1.1

Article Change History

09/02/92 - UPDATED
* To add availability information.

Is there an updated version of the Compatibility Checker to reflect third-party upgrades and broader testing of existing products?

This article has been archived and is no longer updated by Apple.
There is a new version of the Compatibility Checker. Compatibility Checker 1.1 is now available. You can get it from AppleLink, Apple service providers, and Users Groups. The System 7.0 upgrade kits now include it.

Compatibility Checker 1.1 has 165 new records, as well as updated product compatibility information and corrected phone numbers. It also offers compatibility information on third-party drivers.

System 7: When an Application Doesn‘t Support Stationery

Article Change History

08/18/92 - REVIEWED
* For technical accuracy; edited.

The Stationery feature seems to have a counter-intuitive user interface. If I check both Stationery and Locked in a document's Get Info box, and then open the document, I get an untitled document with the contents of the selected Stationery document. Is this how it should work?

This article has been archived and is no longer updated by Apple.
Yes, this is how it should work. But the application must support Stationery for it to work correctly. If the application doesn't provide support, the Finder substitutes fundamental actions. What you see are the Finder actions taken in the absence of Stationery support from the application.

When you double-click a Stationery Pad in the Finder, you open a copy of the document. If a document is marked as Stationery, the Finder checks the application to see if it supports Stationery. If the application doesn't support Stationery, the Finder creates a new document from the template and prompts you for a name. The Finder then makes a copy of the document and displays the copy dialog.

When you open a Stationery document from an application that doesn't support Stationery, an alert box warns that you are opening the Stationery Pad itself, not a copy of it. Opened from the application, you make changes to the Stationery document as if it were an ordinary document. It is possible in such a case to change a Stationery document even when you didn't intend to alter the template.

If the application supports Stationery, the Finder won't perform auxiliary actions. The application takes responsibility for what happens. The specifications for Stationery support require that the application copy the template's contents into a new document and open the document in an untitled window.

Grimes Security Kit: Macintosh LC Requires Two Loops

Here in Sweden, we sell a Grimes Universal Security Kit. It's supposed to fit all Macintosh computers, but it doesn't cover both the Macintosh LC and its keyboard because the kit includes only one loop. Can we get a second loop separately?

This article has been archived and is no longer updated by Apple.
Grimes is in the process of repackaging their security product. The current kit contains one keyboard loop. To use the product on a Macintosh LC, you need two loops. Contact Grimes for additional loops.

You can find the address and phone number for Grimes, Inc. in a separate article in the Tech Info Library.

SchoolBus: File Sharing

This article discusses file sharing using the BOS (Bus Operating System).
This article has been archived and is no longer updated by Apple.
The BOS (Bus Operating System) will not allow different users to access the files of a single user. A student cannot save a file to disk so that another student can access that file. BOS only allows the student to save files and retrieve them under his name and will not allow more than one user to have the same name.

TA46968_Macintosh_Display_Cards_Identifying_PALCompatible_Versions_(TIL08555).pdf

Macintosh Display Cards: Identifying PAL-Compatible Versions

There are PAL versions for the Macintosh Display Cards. The label appends "/A" for NTSC, and "/B" for the PAL version.

Is there a visible difference on the card to identify the PAL version?

This article has been archived and is no longer updated by Apple.
The Macintosh Display Card 8*24 GC (M0122LL/C) has always had PAL capability. The current ROM version is 1.1.

On the other cards, there is no visible difference (8*24 M0507PA/B; 4*8 M0121PA/B). The only change is a ROM revision.

Apple introduced a new ROM for the Macintosh Display Cards 4*8 and 8*24 in July. The card uses sense-pin combinations to determine NTSC or PAL. We ship all new cards with this ROM (version 1.2, part number 341-0868). You can get upgrades for older cards (fee involved; see the August Service Mailing).

PostScript: Printing From a PC

I need to print, on an Apple LaserWriter, some Macintosh PostScript files that were transferred to an IBM. Do you know of any programs for the PC that can send a PostScript file to a PostScript printer (similar to SendPS on the Macintosh)?
This article has been archived and is no longer updated by Apple.
The nature of connections between PCs and printers eliminates the need for a SendPS type of utility. On a Macintosh, SendPS sets up a PAP session with a LaserWriter and downloads the specified file. With a PC, the LaserWriter connects to one of the serial ports directly, or via a network card that allows mapping of COM or LPT ports to the LaserWriter. In either case, you can COPY a desired file to the port to print it.

Assuming your LaserWriter is connected serially, these are the required steps:

1) Set up the COM port with the MODE command. Typical settings are 8 data bits, 1 stop bit, and no parity.

2) With these settings, and assuming the use of COM1, the command looks like this:

MODE COM1:9600,n,8,1,p

Note: You execute this command only once each time you start the computer. Because the settings remain until the next startup, this command is frequently placed in the AUTOEXEC.BAT file.

3) To print a PostScript file to the LaserWriter, use the COPY command: COPY myfile.ps COM1

Improving Server Performance

Which makes more sense to increase network performance when getting files from the hard drive of a file server?

- Upgrade the server to a faster CPU? (e.g. from a Macintosh II to IIfx)

- Add SCSI Cards to speed up performance of the disk drive?

This article has been archived and is no longer updated by Apple.
It depends on what part of the system is currently the bottleneck and how much you want to spend. Since the target is the CPU and I/O, we assume you're already using EtherTalk and not LocalTalk. This is the most obvious first step to improve performance.

The next step depends on what the most important application is on the server. Upgrading the CPU from a Macintosh II to a Macintosh IIfx can help a number of server operations a little, but it won't make dramatic differences. If a high percentage of the server's time is spent waiting for the disk drive to complete seek operations (such as with multi-user database applications), then speeding up this waiting won't do much good, and you should consider a higher performance disk drive. This may consist of a disk drive with faster seeks and throughput, but could also be a caching SCSI card such as the DayStar SCSI PowerCard with several megabytes of cache RAM. Each contributes unique advantages.

A combination of all of these upgrades would give the highest performance improvement. Since we haven't performed any benchmarks on this subject, we can't provide you with real numbers for comparison. Our recommendation is to obtain a caching SCSI card for evaluation and decide if it provides the necessary performance improvements.

Cellular Modems from Cellabs

I would like to use my Macintosh Portable with a cellular phone in the car to access the network in the office. Any ideas?

This article has been archived and is no longer updated by Apple.
Cellabs makes two products that allow you to access your office network using a cellular phone. Both products tie into an existing cellular phone between the handset and base unit.

* One product is Cellmodem 2400. If you don't have a modem, Cellmodem 2400 can provide both 2400 baud modem and Datajack capabilities in one unit.

* Another product, Datajack, allows a cellular phone to work with any internal/external modem you already have.

You can find the address and phone number for Cellabs in a separate article in the Tech Info Library.

MacX Server and X Client Source Code

Is there any way to take the source code of an X application and move it to a Macintosh so that the client piece as well as the server piece both will run on the Macintosh?

I know I can run MacX to another X client, but the X client does most of the processing. I want the Macintosh to do all of the processing.

This article has been archived and is no longer updated by Apple.
No, currently there is no way you can take the X client source code compiled under Macintosh OS and run with the MacX server under Macintosh OS. No X11 library and Xt intrinsics are available for Macintosh OS, and there is no way to compile the X client under Macintosh OS. Only the MacX "server" environment is supported under Macintosh OS.

Tape Backup 40SC: Problems with HD Setup (9/93)

The Tape Backup 40SC Owner's Manual (copyright 1987, 030-5571-A) clearly states on page 29, "Important: Back up and restore to the same device. Don't back up one hard disk and restore to another".

IMPORTANT COMPATIBILITY NOTES:
* The bundled software included with the Tape Backup 40SC is Tape Backup 40SC 2.0.1, which is INCOMPATIBLE with System 7 and later.

* Apple recommends using third-party backup software with the Tape Backup 40SC. Some third-party products that work with the Tape Backup 40SC are Retrospect and Retrospect Remote from Dantz Development Corp., and FastBack Plus from Fifth Generation Systems. Further, using of these applications will not cause the problem detailed below.

This article has been archived and is no longer updated by Apple.
Here is a more in-depth explanation of the manual statement:

When using the Apple Tape Backup 40SC and Tape Backup 40SC 2.0.1 software to do a "Volume" backup, be aware of several factors. The tape backup program puts a "mirror" image of the hard drive onto the tape. In other words, the backup software starts at sector 0 and continues reading to the end of the hard drive. During this process, the backup software writes the data to the tape, sector by sector; any and all bad sectors are written onto the tape as well. This method of backup also copies information such as boot blocks, volume size, and the volume directory.

When the "Restore Volume" command is selected, the software checks the tape for the size of the volume it is going to restore. You are now prompted to select the volume you want to have restored. At this point, the tape backup program verifies that both volumes are exactly the same size. If the volume you are restoring to is smaller than the volume on the tape backup, you get an error message and the backup program won't allow you to continue. If the volume you are restoring to is larger than the tape backup volume, you'll be able to restore, but the volume will appear to be the same size as the original volume. For example, after backing up a HD 20SC using the backup "Volume" option, then restoring it to a HD 40SC, the HD 40SC will appear to have a total of only 20 megabytes of storage.

Different versions of the HD Setup program format Apple hard drives with various amounts of total capacity. HD Setup 1.0 and 1.1 format hard drives with the same number of blocks. HD Setup 1.2 give a different number than 1.0 and 1.1, while HD Setup 1.3 and 1.4 yield yet another different number of blocks. The numbers of blocks also depends on the physical size of the disk (e.g. 5.25" vs 3.5") or manufacturer.

Apple HD Setup 1.4 and later versions format all hard drives of like capacity with the same number of blocks.

Macintosh Monitors: MS-DOS PC Compatibility

Can a Macintosh monitor be used on a MS-DOS personal computer? I have the pinouts for the Macintosh monitors. If I made a special cable to meet the pinout specifications, could it be done?
This article has been archived and is no longer updated by Apple.
The video cards for MS-DOS computers have different timing than the Apple monitors. With the exception of Multiple Scan displays, Apple monitors are locked into a specific scan rate, which matches the Apple video cards, and cannot be changed.

However, many modern PC graphics cards can be made to run with Apple compatible timing, usually through software drivers. You would need to check with the card vendor to ensure compatibility with Apple monitors. Also, check the monitor user's manual for additional information like cable pinouts.

Many third-party monitors adapt to a variety of scan rates, just like Apple's Multiple Scan displays. We do not have a reference list of third-party monitors that are Macintosh and MS-DOS compatible. Contact the monitor manufacturer to determine a monitor's ability to work in both environments. Generally, monitors used with MS-DOS computers are known as EGA-, VGA-, CGA- (or similar "xGA-") compatible.

Macintosh Access to Btrieve on Netware

We have a Novell network (currently upgrading to 3.11) using SoftPC, MagicPC and Btrieve. We would like to use applications that are resident on the Novell server. What can we use to access Btrieve files created in DOS format from a Macintosh? Can we run applications? Will there be a performance penalty?

This article has been archived and is no longer updated by Apple.

Accessing Btrieve files from a Macintosh workstation cannot be done directly from the Mac OS because we don't know of an implementation of Btrieve that is Mac OS compatible. There are other B-tree library solutions like c-tree Plus from FairCom, but they are not file-compatible with Btrieve. There are, however, several solutions for executing DOS programs on a Macintosh, and these could be those same Btrieve-based applications used on the PCs.

The classic solutions for executing DOS applications on a Macintosh are SoftPC (from Insignia Solutions, Inc.) or a DOS coprocessor card. The coprocessor cards, such as the Orange Micro Mac286 or Mac386, are PCs on a card that plug into a Macintosh and are accessed via a Macintosh program. These hardware solutions tend to be faster, but are also much more expensive.

A third and more recent solution is Novell's Netware Access Server. This product installs on the Netware server and allows up to 16 simultaneous virtual DOS sessions to be distributed over the network to workstations. The workstations run client software that provides the DOS session in a Macintosh window. Since you already have a Netware server installed, this might be the way to go.

Performance of each solution depends on the application. The Mac386 card is likely to give the best performance, but this isn't very cost effective if a number of users need them. The performance potential of the Novell solution is good, especially if the Btrieve files are located on the Netware server with the DOS session server. The only network traffic is for user input and screen updates. With a database application, this may even outperform the DOS coprocessor cards.

We recommend that you first try the PC applications with SoftPC, since you already have that. If the performance isn't to your liking, you may wish to try another solution. Either way, it sounds like you're already very close.

Novell Netware: Doesn‘t Support the Apple LocalTalk PC Card

I need the LAN Driver disk for the generation of the IPX shell for Novell 2.15C with AppleTalk PC Card (M2313/A). When IPX is executed, it locks up an IBM P/2 Model 30/286.
This article has been archived and is no longer updated by Apple.
According to Novell, Netware doesn't support the Apple LocalTalk PC card. The only LocalTalk card Netware supports is the Dayna DL/2000 (a replacement for the older NL1000).

The DL/2000, for Standard PC Bus computers, and the DL/2, for MicroChannel computers, are LocalTalk adapter cards that replace Novell's NL/1000 and NL/2 cards. These cards are Novell certified and are ideal for use with DaynaNet and Netware for Macintosh networks. In addition to supporting AppleTalk Filing Protocols (AFP), the cards, along with the DaynaTalk cards, are LocalTalk cards that also carry Netware NCP and IPX protocols. This feature allows the adapter cards to be used in Netware file servers and PC workstations, providing full access to print spooling and administration over the LocalTalk cable.

This article provides information about a non-Apple product. Apple Computer, Inc. is not responsible for its content. Please contact the vendor for additional information.

SNAps: 510 Error on SDLC Connection

Article Change History

10/15/92 - REVIEWED
* Reviewed for technical accuracy.

I'm trying to get an SDLC connection from the SNA*ps Gateway across an Apple Serial NuBus card. The 3270 Emulator instantly put up a 510 error on connect, and the Message log from SNA*ps Admin indicated a successful connection to Host 01.

The Mainframe people at the remote host site got nothing at all on their FEP port. Communications attached a breakout box to the line and said that the Clear to Send line was held low (although I don't believe that was coming from the Serial card).

Should I use port 2 (A or B) on the Hydra cable instead of Port 1A? Can you confirm whether this is the problem?

This article has been archived and is no longer updated by Apple.
As you might already know, the Apple Serial NB cards, as shipped, are configured with ports 1A and 1B as high-speed V.35/RS-422 types of ports, and ports 2A and 2B as low-speed RS-232-C ports. If you plan to use port 1A or 1B also as RS-232-C ports, you have to remove two small components, called R-paks, from the card. Refer to the Apple Serial NB Card Installation Guide for the location of these R-paks. If you use the V.35 modems, you can use port 1A. Otherwise you need to select ports 2A or 2B in the SDLC Line Screen. See if the R-paks were removed from your card, and/or configure the ports correctly, and try again.

Published Date: Feb 18, 2012

Ethernet NB Card and DECnet INIT

In testing the Apple Ethernet NB Card with PATHWORKS to load the DECnet INIT, the system crashes with a bus error. Is a fix available?

This article has been archived and is no longer updated by Apple.
We were able to load DECnet for Macintosh 1.0, and use NetCopy to transfer files from a VAX to our Macintosh without any issues. We also used DECnet for Macintosh 1.1 EFT1 and that also worked fine.

We used a Macintosh IIfx, running system software 6.0.5, 4MB RAM, and DECnet for Macintosh 1.0. Our EtherTalk software was installed from the EtherTalk Installer version 2.5.1 that came with the Apple Ethernet NB Card. The other EtherTalk components and versions are EtherTalk Prep 1.0, EtherTalk Phase 2 version 2.2.2, and A/ROSE 1.1.4.

To troubleshoot further, answer these questions:
- Did this happen on every system? Could you try other systems?
- What is the hardware configuration of the Macintosh?
- What are the system software and network software versions?
- Did you try on more than one Apple Ethernet NB card?
- Do you have any INIT or CDEV, which might conflict with Apple software or DECnet software? You should try with a clean system.

TokenTalk NB Card: SNA■ps and AS/400 Compatibility

Is the TokenTalk NB card compatible with AS/400? Will SNA*ps work with it?

This article has been archived and is no longer updated by Apple.
You can configure the AS/400 with an optional token ring communications subsystem. Each token ring adapter card supports up to 254 devices on the ring. A Macintosh with an Apple TokenTalk NB Card can connect to a token ring LAN and to the AS/400.

A Macintosh running TokenTalk can also communicate with an AS/400 using a product that supports distributed sessions over AppleTalk networks. An example of this is NetAxcess from Andrew Systems.

SNA*ps is fully compatible with the Apple TokenTalk NB Card. In fact, a Macintosh with an Apple TokenTalk NB card can run as a SNA*ps APPC Gateway. Legent Corporation (formerly by Spectrum Concepts) and Andrew Systems developed products to take advantage of this SNA*ps APPC Gateway. MacXCOM 6.2 from Spectrum Concepts is fully compatible with SNA*ps APPC API and provides Macintosh users with File Transfer, Remote AS/400 Job entry, and a Report Writer. TokenAxcess from Andrew Systems allows a Macintosh in a token ring to access the AS/400 as a 5250 workstation.

To locate a vendor's address and phone numbers, use the vendor name as a search string.

Article Change History
23 July 1993 - Company title changed from Spectrum Concepts to Legent Corp.
9 February 1993 - Updated, spectrum Concepts acquired by Legent Corporation.

SNA■ps: Third Party Token Ring Cards and Routers

1) I just want to verify that the SNA*ps client piece will run with third-party token ring cards.

2) When running SNA*ps Gateway (on an Apple token ring card), are there any issues related to accessing mainframes across routers such as Cisco?

This article has been archived and is no longer updated by Apple.

1) SNA*ps Gateway requires Apple Token Ring cards. It doesn't support third-party Token Ring cards. SNA*ps Gateway communicates with distributed Macintosh computers via ADSP, so the distributed Macintosh computers can have third-party Token Ring cards as long as they are TokenTalk compatible.

2) The Cisco router provides both AppleTalk routing and source routing bridging, so it should work with SNA*ps running either as a gateway or distributed SNA*ps 3270 on AppleTalk (LocalTalk, EtherTalk, and TokenTalk) networks.

To locate a vendor's address and phone number, use the vendor's name as a search string in the Tech Info Library.

DAL Server: MVS/VTAM

I'm about to purchase DAL for VTAM. Is the following information correct?

1) TCP/IP is not currently supported.

2) SNA support is available via Netway 2000, Avatar, and MacIrma, but not via SNA*ps.

3) There are no extra pieces needed on the IBM (in addition to DAL). I have experience with a few other products that require LU6.2. DAL for VTAM does not require LU6.2. DAL for VTAM doesn't run under CICS.
This article has been archived and is no longer updated by Apple.
1) DAL 1.3 only supports MacTCP connection to IBM host systems running VM.

2) The following connections are available using the 3270 display station (LU2) communications protocols:

* MacDFT Coax/Twinax, TokenTalk NB Card, or Serial NB Card
* Netway 1000/2000
* MacMainFrame
* MacIrma

Additionally, with SNA*ps, you can define a connection using the APPC display station (LU6.2) communications protocol. Use this connection if your Macintosh connects to an IBM mainframe through a LocalTalk or Ethernet network which has access to a SNA*ps 1.0.1 gateway.

3) Correct. CICS 1.7 or later is optional, and is required only if you are using the CICS Passthru program to access the VTAM server.

MacX Over DECnet without PATHWORKS (1/95)

I want to run MacX on a Macintosh IIci (with Ethernet board) to a VAXstation using the DECnet protocol. Is there a software package to get the DECnet services? I know that I can use MacX with PATHWORKS to run DECnet, but I'm not sure if DEC wrote specialized software. In my case, buying PATHWORKS is not an option.

This article has been archived and is no longer updated by Apple.
Since you aren't buying PATHWORKS for Macintosh, you need to get DECnet software called TSSnet from Thursby Software (Alisa also sells this Thursby TSSnet package). The VAXstation should be running DECnet, which comes with VAX/VMS. You miss the following two things by doing it this way:

* PATHWORKS includes DECwindows fonts that you will need when you run DECwindows clients. If you buy MacX from Apple, you won't get these fonts.

* PATHWORKS provides a DECnet object called MSAX$CLIENT, which allows automatic execution of DECwindows clients from the remote Macintosh running MacX server. Without this DECnet object (which does not come with standard DECnet), you must:

* Log on to the VAX using a terminal emulator.

* Define a DECwindows display using the DCL SET DISPLAY command.

* Use RUN/DETACH or SPAWN to execute the DECwindows client.

DAL: Out-of-memory Error Due to Application‘s List of Tables

I'm evaluating DAL on an IBM 3090. I would like to hard code the name of a specific table within a query. Is there a way to avoid maintaining a list of tables in memory that causes an out-of-memory error due to the large list of tables available?

I've been able to use the Excel add-in to do the following tasks:

- Connect to the mainframe
- Access the DAL server
- Open sqlds
- Open the iu database

At this point, the Excel data access add-in appears to be creating a local copy of information about all the tables within the iu database on the mainframe. Why is this necessary? Since the combination of the system, the Finder, and Excel use up about 3.4MB of the 4MB available on our Macintosh IIci 4/80, I get an out-of-memory message box with an OK button.

ClearAccess actually does the same sort of thing. When creating a new query, it fills one component of the query-building window with a scroll box containing all the tables that I have in my view of the iu database. Since I'm running only a desk accessory, there is enough memory for this to happen.

This article has been archived and is no longer updated by Apple. DAL engineering confirmed that this is an application implementation problem, not a DAL problem. DAL doesn't require a list of tables kept locally on the workstation.

We recommend that you discuss this issue with the application vendors.

You can find contact information for the various vendors by clicking the Library Index button to view the folder structure in the Tech Info Library. An alphabetic listing of vendors is in the Third Party Company Directory folder.

Ethernet and Routers versus LocalTalk Bridges

I am looking for some network performance information. Specifically, I need to know what the performance advantages are for putting in Ethernet and routers versus LocalTalk bridges to extend a network beyond the standard LocalTalk limitations. My network is in a publishing environment that deals with many large color graphics and images.

The nodes are all Macintosh II series, mostly high-end systems. They are scattered over a number of different floors in a building. I have 48 nodes now, and expect that number to grow significantly.

This article has been archived and is no longer updated by Apple.
It's difficult to make specific statements about the viability of LocalTalk over Ethernet or Ethernet over LocalTalk without knowing more about the customer's environment. Two important factors to consider are the number of potential users on the network, and the actual type of work they do over the network (that is, file sharing, mail, database, and so on). It's not too difficult to come up with a few graphs to show the difference between LocalTalk and Ethernet transfer rates, but it really doesn't tell the whole story or justify the expense of moving to Ethernet.

LocalTalk uses CSMA/CA and Ethernet uses CSMA/CD. A certain amount of overhead is associated with CSMA/CA which is not needed in a CSMA/CD (Ethernet) environment. The bandwidth of a LocalTalk network can be dominated by a single node doing a single file transfer. Ethernet has plenty of bandwidth available, which makes domination by a single node almost impossible. On the other hand, LocalTalk is basically free and Ethernet requires a significant investment in hardware.

Ethernet is definitely the best choice for anyone contemplating large numbers of users accessing a shared resource and/or anyone who may have significant data transfer requirements. It sounds like you fit this description. Remember that networks usually grow larger and more complex. With more demanding network-based applications predicted for the future, LocalTalk may be a viable topology only for small workgroups that only transfer an occasional file and/or read mail.

AppleTalk Over X.25

Is it possible to connect two AppleTalk networks using X.25 and two half-routers (like a Shiva TeleBridge)? I understand that this would be much slower than pure LocalTalk, but it might be a nice alternative to a 9600-baud NetModem.
This article has been archived and is no longer updated by Apple.
With the Apple Internet Router 3.0 Wide Area Extension options, you can connect geographically remote workgroups using wide-area telecommunications links. The AppleTalk/X.25 Wide Area Extension (available separately) enables two or more AppleTalk networks to communicate through an X.25 communications link. This wide area extension includes:

* Offers a wide variety of X.25 parameter settings, enabling you to implement the most effective X.25 service.

* Provides a set of standard profiles for the major public packet-switched networks worldwide.

* Allows you to create your own customized profiles for any public or private data network.

Apple's X.25 product, MacX25, can't route AppleTalk over a packet-switched network. You can also explore third-party solutions. Keep in mind that the PDN (Packet Data Network) provider's charges are based on, among other things, the size and number of packets.

One AppleTalk X.25 WAN routing scheme is from Access Privilege, a company in France. Their product named "The Link" is based on the CommToolBox and works with the Apple Internet Router. It provides routing over a variety of links including X.25, and eventually ISDN.

One of the more commonly used AppleTalk tunneling solutions comes from DEC. GatorBox and cisco offer good solutions.

In general, Apple does not control how third parties choose to implement routers and other such products based around AppleTalk. With every solution, you check with the supplier to find whether their product serves your needs. It's a good idea to request testimonies and account referrals.

The rest of this article lists third-party router manufacturers who can route AppleTalk over X.25.

Ungermann-Bass, Inc.
A remote router and software for an AppleTalk hub work with the company's Access/One multiprotocol hub system. The ASM 8320 plugs into the same multiprotocol hub as the company's MaxTalk--a 16-port, twisted-pair AppleTalk hub--to connect physically separated networks over several kinds of media. The router connects sites over standard serial lines, 56-Kbpsleased lines, high-speed T-1 lines, or X.25 packet-switched networks at data transfer rates of up to 2.05MBps.

The two-port version with router software can route packets locally between AppleTalk networks using any combination of LocalTalk, Ethernet or Token Ring. A separate DOS-based management program lets users configure the router to filter and restrict traffic according to protocol type, port number, or source or destination address. Managers also can identify high-priority packets from a particular address or of a certain type that the router will forward immediately.

New MaxTalk software adds AppleTalk Phase 2 support as well as Phase 1-to-Phase 2 routing to the company's combination AppleTalk hub and TCP/IP gateway. Improved security lets network administrators control access to printers and file servers.

cisco Systems, Inc.
Like other cisco routers, the AGS+ routes a number of protocols, including TCP/IP, DECnet, OSI, XNS, Apollo Domain, Novell IPX, Banyan VINES, 3Com 3+Open, Ungermann-Bass Net/One, X.25, DDN X.25, and AppleTalk. Optional concurrent bridging and source-route bridging are available to handle non-routable protocols such as DEC's LAT and IBM's SNA and NetBIOS. It also supports multiple routing protocols (RIP, IGRP, BGP, EGP, RTMP) and the Simple Network Management Protocol (SNMP) for remote network monitoring.

Proteon Corp
Proteon Corp offers the ProNet CNX series of RISC-based communications routers. The ProNet CNX series uses a special multiport shared-memory architecture and AMD's (Advanced Micro Devices) 29000 RISC processor. The CNX 500, the first in the series, runs at 25,000 packets per second. The router is intended for IBM SNA/multiple-protocol environments, particularly for work groups needing to move from 16M-bps token ring backbones to 100M-bps Fiber Distributed Data Interface (FDDI) backbones. The device routes IBM-environment messages into IPX (Novell Netware), OSI, DECnet, AppleTalk, XNS, and TCP/IP protocol stacks; it supports T1/E1 lines, X.25, and frame-relay fast-packet switching for WANs.

NCR Comten
Mainframe vendor NCR Comten sells a line of intelligent communications servers, the Open Network System (ONS), that function as a freestanding OSI-based backbone for large heterogeneous environments. ONS integrates mixed systems to reduce the amount of interconnecting equipment. It allows growth and control of enterprise-wide computing by offering a configurable and scalable system that is built on industry standards: Intel Corp. processors, MicroChannel bus, SCSI connection, and the UNIX System V operating system.

ONS offers concurrent bridging and routing capabilities. It supports AppleTalk, NetBIOS, Netware IPX, OSI, SNA, TCP/IP, and 3Com 3+ XNS protocols. It supports the RS-232 and RS-422 serial, T1, X.25, and SDLC WAN interfaces. It also supports Stp and token ring source-

routing.

BBN Communications
BBN Communications markets the T/200 IPR as part of its internetwork product portfolio. The T/200 is a multi-protocol, multi-media router that supports such protocols as TCP/IP, DECnet, XNS, IPX, AppleTalk, and X.25 in addition to Spanning Tree bridging. The T/20 and T/200 IPRs are a family of products which can be used in the same network or internetwork.

AT&T Computer Systems
AT&T Computer Systems enhanced its Datakit II Virtual Circuit Switch line by adding token ring support, support for AppleTalk networks, and by including access to multiple hosts. Release 2.0 of the product includes the capacity to relay switch, two-way communication between Datakit terminals and X.25 hosts on public and private packet networks. Disk storage was increased to include support of a 40MB SCSI hard disk and tape subsystem. Current users of the product can upgrade. An optional offering is the Maintenance and Redundancy Control Module, an interface which lets you switch the unit from a primary network to a backup.

To locate a vendor's address and phone number, use the vendor name as a search string.

Macintosh: Wyse 60 Terminal Emulation

I am currently using Motorola Models 3640 and 3840 mid-range computers. The PCs connected to them use a Wyse 60 terminal emulation package from Motorola. Motorola offers no support for the Macintosh. They also provide file server/printer server access for PCs, but not for Macintosh computers. I understand that Motorola bought Pacer software technologies to provide these services on the Macintosh.

I need to locate a vendor that offers the Wyse 60 tool to use with PacerTerm for Macintosh terminal emulation.

This article has been archived and is no longer updated by Apple.
We are not aware of an available Wyse 60 tool that PacerTerm could support. Here are two alternatives:

- Wyse 60 Support within the PacerLink Software

PacerLink software (which is available now to OIR as a preferred customer) doesn't support Wyse 60 directly. Pacer engineers told us that many customers use the ADDS 60 option in place of Wyse 60, but it doesn't work in all instances. It's definitely worth trying.

- A Different Terminal Emulation Package that Supports Wyse 60

We realize that this may not be an alternative in your environment, but you may want to consider a different terminal emulation package which does support Wyse 60. Investigate Term from Century Software or MacEmulate from TLC.

On AppleLink, you can find contact information for the various vendors by clicking the Library Index button to view the folder structure in the Tech Info Library. An alphabetic listing of vendors is in the Third Party Company Directory folder.

TA46992_System_Sending_PostScript_Files_to_a_LaserWriter_(TIL08587).pdf

System 7: Sending PostScript Files to a LaserWriter

Article Change History

08/25/92 - REVIEWED
* For technical accuracy.

Do you know of a PostScript file download utility that works with System 7 and the System 7 LaserWriter drivers? SendPS version 2.1, doesn't work with the new drivers. This is more important than ever now that we can save a PostScript file from the Print dialog box.

This article has been archived and is no longer updated by Apple.
The new LaserWriter Utility program can download PostScript files to a LaserWriter via an option in the Utilities menu.

AppleTalk Update-Based Routing Protocol (AURP)

What is AURP?

This article has been archived and is no longer updated by Apple.
Apple has been working with the IETF, and router vendors to provide enhancements to the AppleTalk Phase 2 routing protocol. The proposed protocol to provide better routing in large wide-area network environmentsis called "AURP."

AURP stands for Apple Update-based Routing Protocol. AURP is the routing information propagation protocol used for full "plug and play" functionality of AppleTalk. This protocol was designed to provide a continuum of options between the static and dynamic cases. In its most dynamic mode, it is functionally equivalent to the current AppleTalk routing information protocol (RTMP and ZIP).

Information regarding this product can be found in Product Information on the Apple Computer, Inc web page.

Token Ring: 16MBps Over Synoptics UTP

Article Change History

02/09/93 - UPDATED
* h-athree Systems, Corp. now Asante Technologies, Inc.

Is there a solution for connecting our Macintosh II series to a 16MBps Token Ring to an IBM system? We have a Synoptics Model 3000 concentrator (Lattisnet) on unshielded twisted pair, and we would like to connect our Macintosh computers to this Token Ring to do 3270 terminal emulation and DFT.

This article has been archived and is no longer updated by Apple.
Synoptics confirmed that its Model 300 Concentrator supports 16MBps Token Ring. You will need the UTP (Unshielded Twisted Pair) Token Ring Host Module model 3505.

On the Macintosh, you need one of the following Token Ring adapters:

- Tri-Data LanWay 16/4 Family: This is a 16/4 Token Ring (IEEE 802.5) LAN option that consists of two adapters--one for the Macintosh SE/30, and one for the Macintosh II family. Equipped with the Texas Instruments TMS380C16 Token Ring Processor, the LanWay Token Ring card can operate at both 16MBps and 4MBps in a single adapter. Software switches the card between the two speeds. For high-performance operations, Tri-Data Systems provides 128K of onboard RAM for multiple transmit and receive operations. The board is TokenTalk compatible, so all AppleTalk LAN operations are compatible with the cards.

- Asante Technologies (formerly h-three Systems, Corp.) MacRing NB 16/4: This is an expansion card (with firmware and software) that connects Macintosh II computers to 16MBps or 4MBps Token Ring networks. The card's speed is hardware- or software-selectable. MacRing NB 16/4 supports third-party software for 3270 connectivity to IBM mainframes and 5250 connectivity to IBM midrange systems over Token Ring networks. It supports AppleTalk Phase 2, IEEE 802.2 LLC (Types 1 and 2) and IEEE 802.5 Token Ring protocols. It supports the Apple LLC IPC interface and IBM source routing. The package consists of the MacRing NB 16/4 expansion card, software, and downloadable firmware on a 3.5-inch disk, a user's guide and a one-year warranty.

You will also need a 4/15MB Medial Filter, such as those offered by Black Box. The media filter connects the Macintosh computers to the MAUs or the Synoptics Token Ring Host Module. It converts the Macintosh's DB-9 connector to a twisted-pair RJ-45 connection.

To locate a vendor's address and phone numbers, use the vendor name as a search string.

System 7: Installing LaserWriter Drivers to Work with System 6

Article Change History

08/18/92 - REVIEWED
* For technical accuracy.

How do I install the new LaserWriter 7.0 drivers to work properly with System 6?

This article has been archived and is no longer updated by Apple.
To properly install the new LaserWriter 7.0 drivers under System 6 or later, be sure to use the Installer found on the Printing Tools disk or in the Printing Tools folder (if using a Network Installer found on a local AppleShare File Server). Using the Installer ensures that Print Monitor (which allows printing to a LaserWriter in the background) will work under system software version 6.0.5 or later with MultiFinder.

Note that if you're using the Installer from a floppy disk, you don't need to restart your Macintosh. The Installer can install "live" over system software currently in use.

Follow these steps:

1) Launch the Installer.

2) Click the OK button when the opening display screen appears.

3) You are now at the Easy Install screen. You can click Install to update all of the printer drivers you have currently installed. Otherwise, click on the Customize button to choose individual printer drivers.

4) Once you make your choices and click the Install button, the Installer installs the software and prompts you to quit. A restart is not necessary.

5) Please note that the default (suggested) memory size for Print Monitor is 80K.

Note: We recommend system software version 6.0.5 or later when using version 7.0 drivers. Version 6.0.8 comes with version 7.0 drivers. Anything below version 6.0.5 may not be fully compatible.

Macintosh: Connecting to SAG‘s Natural Connection

I want connect a Macintosh directly to an IBM 3174/3274/3276 TCU using Type A coax cabling.

The communication protocol required is IBM 3270 D.S. with support for CUT and DFT modes. There must be file transfer facilities which interfaces with FT/TSO on the IBM host. The software must also be compatible with SAG's Natural/Connection software.

I'm interested in trying MacDFT with Coax/Twinax card, but I need to know if MacDFT is compatible with SAG's Natural/Connection software.

This article has been archived and is no longer updated by Apple.
Software AG does distribute a "Natural Connection for the Macintosh" (and for OS/2, and for MS-DOS). It requires a minimum of a Macintosh Plus, with 1MB of RAM and 2 floppies. Their Macintosh application consumes from 348K of RAM (B/W) to 640K (color) or more depending upon the font selected. For color or MultiFinder support you must use Macintosh System Software 6.0.4 or later. The host Natural software must be version 1.2 or 2.1.

The hardware supported include the Apple Coax/Twinax card, DCA's MacIrma, and Avatar's MacMainFrame. AppleTalk support is provided via the Netway 1000 or 2000. The host and client software also supports dialup connectivity.

For More information, search under: "Software AG"

AppleWorks: Printing a Text File

The Appleworks option to print to "a text (ASCII) file on disk" does not put carriage returns at the end of each line. It is designed to let the user create a file which can be used with other (ASCII) word processors.
This article has been archived and is no longer updated by Apple.
If you want to use Appleworks for electronic mail or other applications which require a carriage return at the end of each line, here's how:

From the Main Menu:

Choose "5. Other Activities."

Choose "7. Specify Information about your Printer."

Choose "2. Add a Printer."

Choose "4. Apple Silentype."

Name the printer "EMail" (or name of your choice).

Choose "7. Print onto disk or on another Apple."

Press Escape 3 times to return to the Main Menu.

Now, when you wish to print a file to disk with carriage returns at the end of every line, choose the printer "EMail."

Notes:

1) The Apple Silentype was chosen for the "EMail" printer because it accepts no printer control codes. Therefore, the file that is created contains only text with the appropriate carriage returns.

2) This works for IIIEasy Pieces as well.
Published Date: Feb 18, 2012

Personal LaserWriter LS: Use Prep with System 6.0.7 (8/93)

Do the production disks for Personal LaserWriter LS include a Personal LaserWriter LS icon and a LaserWriter Prep icon? I downloaded the driver from AppleLink and the Prep file wasn't included. I couldn't get it to work on System 6.0.7 without Prep.

This article has been archived and is no longer updated by Apple.
The Personal LaserWriter LS Prep file is in fact a "serial" driver needed for systems running System Software 6.0.7. System 7 contains this new serial driver, making the prep unnecessary.

There are two versions of the Personal LaserWriter LS "printer" driver: the one shipping originally with the printer, version 1.0, and the latest version that ships with System 7, version 7.0. The System 7 driver is preferred as it is faster and contains solutions to earlier problems; this version is compatible with systems running System Software 6.0.7 when used with the (version 1.0) Personal LaserWriter LS Prep file.

A/UX: Transferring Binary Data to Macintosh OS (8/94)

I want to transfer UNIX files that contain binary data (but are not executable) to the Macintosh environment. Normally, the linefeeds in these files are converted to carriage returns, but I don't want to let that happen. Any hints?

This article has been archived and is no longer updated by Apple.
By default, the A/UX file manager converts a line feed into a carriage return when copying a "TEXT" file from an A/UX partition to a Macintosh HFS partition. If the source file was binary executable or a non-executable data file, A/UX file manager copies it intact (without conversion).

In this case, make sure the source file that's going to be copied from an A/UX partition is a Non-TextEditor document (although you want to make sure it IS binary data). The file type can be shown by "Get Info" or the icon on the desktop.

If you are sure it's binary data but you are shown a "TextEditor" document, you have to use the A/UX "setfile" (set attributes for Macintosh files) utility to change its type and creator.

Here is an example: the /usr/lib/font/ftS is a binary data file, but it shows a "TextEditor" document via "Get Info" or icon. Before copying it (without any conversion) to a Macintosh OS HFS partition, do the following to change its file type to binary and creator to A/UX:

```
# setfile -t"BIN " -c"A/UX" ftS
```

NOTE: The file type and creator must be exactly 4 characters long including SPACES.

A/UX: FASYNC And Other Asynchronous Flags Supported (8/94)

Is the FASYNC signal supported in A/UX?

This article has been archived and is no longer updated by Apple.
A/UX supports asynchronous signals (such as FASYNC) on sockets. An asynchronous socket implies that requests will not block.

To receive signals on sockets however, you must do a SIOCSPGRP ioctl call, or a F_SETOWN fcntl call on the socket that will be receiving signals.

AppleShare IP 6.x: Some Mail is Misrouted to Postmaster

When an AppleShare IP 6.x mail server obtains email using the POP (Post Office Protocol) account collection method, some email is sent to the Postmaster instead of the intended recipient.
This article has been archived and is no longer updated by Apple.

Symptom

When using the POP mail collection feature of AppleShare IP 6.x mail server to get email from an ISP's (Internet Service Provider) mail server, some email is sent to the Apple Share IP Postmaster's mailbox instead of the intended user's mailbox. This happens most often with mailing lists.

Products affected

- AppleShare IP 6.2 and later

Solution

This misrouting of email is inherent in the way that POP delivery works. To avoid this situation, use SMTP (Simple Mail Transfer Protocol) to have email delivered to your AppleShare mail server. If do not have a dedicated Internet connection, AppleShare IP 6.0 and later provide ETRN (Extended Turn), which can query your ISP's mail server periodically for new email. ETRN is an extension of SMTP, so all of the SMTP commands are maintained when your server connects to your ISP. For details on setting up ETRN with an intermittent connection, see article 30570: **"AppleShare IP Mail Server: Dialup Send & Receive Setup."**

Note: For an explanation of this limitation of the POP collection method, see article 86030: "**POP Mail Collection Relies on Header Information.**"

Apple Monochrome Monitors: Dot Pitch Not Applicable

What are the dot pitch specifications for Apple's monochrome monitors?

This article has been archived and is no longer updated by Apple.
The monochrome monitors do not use dot pitch.

Dot pitch is a specification for the placement of the three (red, green and blue) dots that make up one color pixel. Since the monochrome image is made of only one dot, there is no need for a pitch specification since that one dot will be the entire pixel.

LaserWriter: Clarifying Serial Switch Documentation

The LaserWriter IINTX manual says that revision 3.0 ROMs can switch between ports using software. The manual says I can disable the RS-422 port to connect an IBM to the RS-232-C port, but it's not clear whether the RS-422 and the RS-232-C ports can be switched while using the IBM.

I have been disabling the RS-232-C port by sending the following program to the printer from the IBM:

```
serverdist begin 0 exitserver
statusdict begin
25 0 0 setsccbatch
25 0 0 setsccinteractive
```

This sets the serial port to a null baud rate. The manual states that the RS-422 port can then be reenabled by typing the same program but using 9 instead of 25 and substituting the desired baud rate for the first zero and the Options Number from the chart labeled C-5 for the second number. This is found on page 141 of the LaserWriter IINTX manual.

However, in apparent contradiction to this, the LaserWriter Reference Manual from Addison Wesley states on page 143 that the setsccbatch and the setsccinteractive commands use the port assignment for the first digit, the baud rate for the second digit, and the parity for the third digit (not the options number!)

Is this third digit supposed to be the options number from the LaserWriter IINTX owners manual, or is it the Parity from the listing of parity digits available on page 144 of the LaserWriter Reference Manual? What IS the options number or the parity selection?

I also am having trouble with the baud rate selection for the AppleTalk port. AppleTalk is supposed to be 235K baud, but there is no selection above 56K baud.

This article has been archived and is no longer updated by Apple.
The setsccbatch and setsccinteractive operators set a port's baud rate, but for asynchronous communications only. More specifically, they set the rate used when the hardwareiomode is set to 0. The only time AppleTalk communications are affected by these operators is if the baud rate of the 9 (or 8) pin port is set to 0.

Setting a port's baud rate to 0 has the effect of disabling it entirely, whether asynchronous serial or AppleTalk is in use. To reactivate the port, either set the baud rate to whatever is desired, or for AppleTalk, set the hardwareiomode to 2 and don't bother with the baud rate.

Page 141 of the LaserWriter IINT/IINTX Owner's Guide contains a misleading paragraph that states the RS-422 port is reactivated by setting its baud rate. You could, in fact, enable it this way for asynchronous communications, but AppleTalk can only be activated by setting hardwareiomode to 2.

As for the apparent contradiction between the Addison Wesley manual and the Owner's Guide, they're both right - they just tell a different part of the same story. The options number used with setsccbatch and setsccinteractive is an 8-bit value made up of 4 separate bit-fields; 2 bits for parity, 3 bits for flow control, 2 bits for data bits, and 1 bit for stop bits, in that order. They are arranged with parity being the least significant 2

bits, and stop bits being the most significant bit of the byte. Since each parameter can be computed and set independently, any value from the table on page 153 can be used individually. Though it's more common to add each parameter's value and set them all at once, it is possible to use something like "3" for the options value to set mark parity. This will leave the other parameters as they are. Likewise, data bits could be set to 8 by using "64" as the options value. Parity, flow control and stop bits would remain unchanged.

Currently the easiest way to set LaserWriter parameters is to use a PostScript downloading utility to send PostScript programs written in a word processor. This downloading function is available in recent versions (7.0 or later) of the LaserWriter Font Utility. A more direct method is available with Microsoft Word by using its PostScript style. Text that is of the style PostScript will be passed to the LaserWriter as a PostScript program instead of as text to be printed.

DAL: Support for PICK Database

I'm interested in using DAL with a PICK database, or rather a Unidata PICK clone that runs under UNIX and supports SQL (which the real PICK does not).

Have you heard of any such database? If not, do you have any feel for how long it takes to write a new DAL server based on the DAL server package?
This article has been archived and is no longer updated by Apple.
There is no DAL server/adapter for PICK databases.

There is no facility to enable non-licensed creation of servers or DBMS adapters to work with DAL.

Mac OS 9: Apple DVD Player Opens Before Multiple User Login

While the computer is starting up the Apple DVD Player application opens before the Multiple Users login screen appears.
This article has been archived and is no longer updated by Apple.

Symptom:

The Apple DVD Player application opens before the Multiple Users login screen appears.

Products Affected:

- Power Mac G4 (Gigabit Ethernet)
- Power Mac G4 (Digital Audio)
- Power Mac G4 (QuickSilver)
- Power Mac G4 (QuickSilver 2002)
- iMac (Summer 2000)
- iMac (Early 2001)
- Power Mac G4 Cube
- PowerBook G4
- PowerBook G4 (Gigabit Ethernet)

This issue happens when Multiple Users is turned on, and a DVD-Video disc is in the DVD-ROM drive when the computer starts up.

Solution:

Remove the DVD-Video disc from the DVD-ROM drive before shutting down or restarting the computer.

or

Open the Extensions Manager control panel and turn off the DVD AutoLauncher extension. To play a DVD video, open Apple DVD Player (in the Apple menu).

Macintosh: Terminal Emulators for UNIX Systems

Article Change History

08/31/92 - REVIEWED
* For technical accuracy.

I need a UNIX terminal emulator (to run on a Macintosh) that will do the following:

- Toggle between 80 character mode to 132 character display
- reverse video
- Downline load ASCII files

This article has been archived and is no longer updated by Apple.
UNIX systems support almost all types of terminal available. One of the most popular terminal types supported is the Digital VT100 series. Lots of Macintosh programs support this terminal type, especially the later ones which use the Communications ToolBox.

MacTerminal 3.0 allows you to use the VT102, or the VT320 Tools. In the Screen setting, you can toggle between 80/132-columns, and select inverse video. In the File Transfer setting, you can select files transfer using the Text Tool, or the XModem Tool.

Pacer's PacerTerm and Synergy's VersaTerm-Pro also use the Communications ToolBox and support other Tools besides the Apple Tools.

For more information, search on the above product names.

PATHWORKS 1.0: No Official Support for HP LaserJet

Does PATHWORKS 1.0 support HP LaserJet? Does the print driver from the PATHWORKS (either 6.0 or 7.0) support LaserJet?

This article has been archived and is no longer updated by Apple.
Officially, PATHWORKS 1.0 Print Services only support following PostScript printers:

Printer	Connected to the VAX computer through
Digital LPS20	Ethernet
Digital LPS40	Ethernet
Digital LPS40 Plus	Ethernet
Digital LN03R	Serial Connection

Apple printers: LocalTalk/Ethernet bridge or an RS-232 serial connection

LaserWriter Plus
LaserWriter IINT
LaserWriter IINTX

The PATHWORKS print drivers are for the above PostScript printers only.

If you need more specific information or you have enhancement requests, contact Digital Technical Support directly.

.Mac iDisk: Filenames Appears as Random Characters

Files copied to iDisk must use either MacJapanese or MacRoman character sets.
This article has been archived and is no longer updated by Apple.

Symptom

Files on your iDisk appear to have filenames composed of random characters when you connect to your iDisk using Apple File Protocol (AFP).

Solution

1. If a filename appears to be composed of random characters after you copy it to your iDisk, check the original to see if it is encoded using Chinese or another character set.
2. If the file is encoded using something other than MacJapanese or MacRoman character sets, change character sets to rename the file using either the Roman or Japanese character sets.

Keep in mind that special characters in filenames can cause problems on some computers. If using the Roman alphabet, use only uppercase letters (A-Z), lowercase letters (a-z), numbers (0-9), and the underscore (_) in your filenames.

TA47017_PASCAL_II_Line_Feeds_(TIL00861).pdf

PASCAL II 1.1: Line Feeds

Pascal always prints a LF after a CR; to suppress the LF you have to execute LINEFEED.CODE. (This only works for the PRINTER:.)
This article has been archived and is no longer updated by Apple.
There is a way to override this feature for REMOUT: when using a Super Serial Card and UNITWRITE, but not when using WRITE and WRITELN.
Published Date: Feb 18, 2012

VAXshare: Printer Services and LaserWriter Zones

Apple Technical Support says that a "VAX can be in a different zone than the LaserWriter printers, but there can only be one zone for the non-extended LocalTalk network where the LaserWriter printers are".

Referring to the following diagram, can I configure all printers serially connected to the VAX to be in Zone A and LaserWriter X to be in Zone B, and LaserWriter Y in Zone C (assuming I also upgrade FastPath to support AppleTalk Phase 2)?

VAX (PATHWORKS 1.0) ** Zone A **
| Ethernet

| |
FastPath (with Phase 1 support) Internet router (Phase 1,2 support)
| |
---------- LocalTalk network ----------LocalTalk network
LaserWriter X ** Zone B** LaserWriter Y ** Zone C **

This article has been archived and is no longer updated by Apple.
It is not clear from your description that the printer connected to the VAX serially is a Digital PostScript printer or an Apple LaserWriter. Nevertheless, the answer is Yes, you can configure the printers in those zones.

Here is more information:

1. If you connect the LaserWriter directly to the VAX computer as a serial device, follow the following steps from the Digital System Administrator's Guide:

1.1. Connect a straight through RS-232 cable from the 25 pin connector on the back of the LaserWriter to the serial output connector on the VAX computer.

1.2. Set the printer switches as follows:

Printer Settings
------- --------

LaserWriter 4 position mode switch to 9600
LaserWriter Plus 4 position mode switch to 9600
LaserWriter IINT
1 Up
2 Down

LaserWriter IINTX
1 Up or Down
2 Down
3 Up
4 Up
5 Down
6 Down

1.3. Set the VMS terminal line to which the printer is connected by entering the following command:

$ SET TERMINAL device-name:
_$ /NOAUTOBAUD/NOBRDCSTMBX/NOBROADCAST-
_$ /DEVICE_TYPE=UNKNOWN-

```
_$ /NODISCONNECT/NOECHO/EIGHT_BIT/NOESCAPE-
_$ /FORM/FULLDUP-
_$ /HARDCOPY/HOSTSYNC/LOWERCASE/PASTHRU/PERMANENT-
_$ /SPEED=9600/TAB/TTSYNC/TYPE_AHEAD/NOWRAP
```

For subsequent reboot of the VAX, add the above line to the SYS$STARTUP:SYSTARTUP_V5.COM file. Be sure you enter this line before the SYS$STARTUP:MSA$STARTUP.COM line.

1.4. Add the VAXshare LaserWriter printer service. The following example creates a LaserWriter printer service called "Serial LaserWriter" with a queue name, "LW_SERIAL".

```
$ ADMIN/MSA
MSA$MANAGER> ADD PRINTER "Serial LaserWriter"-
_MSA$MANAGER> /QUEUE=LW_SERIAL/DEST=device_name:
MSA$MANAGER> EXIT
```

1.5. To create the queue and start the service, enter the following command:

```
$ ADMIN/MSA START PRINTER "Serial LaserWriter"
```

2. If the printer connected to the VAX is a Digital PostScript printer, you need to specify the Printer Service name and VMS queue name to add a VAXshare printer service for it. You need to know the name of an existing VMS printer queue for which you want to set up printer services. If you do not have an existing queue, create one by using the standard VMS commands. The printer service will appear in the zone the VAX is in, which is Zone A in your example.

```
$ ADMIN/MSA
_MSA$MANAGER> ADD PRINTER "Digital printer"-
_MSA$MANAGER> /QUE=LPS_20_POST-
_MSA$MANAGER> /PARAM=(DATA_TYPE=PostScript)-
MSA$MANAGER> EXIT
```

3. Assuming that your FastPath is upgraded to support AppleTalk Phase 2, both the LaserWriter printers in the LocalTalk network can be added to VAXshare print services. The /DESTINATION will be used to specify the zones where the printers reside. For example, the following defines the LaserWriter X and Y in Zone B and Zone C as LaserWriter X and Y Spoolers.

```
$ ADMIN/MSA
MSA$MANAGER> ADD PRINTER "LaserWriter X Spooler"/QUEUE=LWX_PRINT-
_MSA$MANAGER> /DESTINATION="LaserWriter X@Zone B"-
_MSA$MANAGER> /DEFAULTS=(FLAG, TRAILER, FORM=LTR_12)-
_MSA$MANAGER> /FONTS=MSAP$FONTLIST_APPLE35.TXT
_MSA$MANAGER> ADD PRINTER "LaserWriter Y Spooler"/QUEUE=LWY_PRINT-
_MSA$MANAGER> /DESTINATION="LaserWriter Y@Zone C"-
_MSA$MANAGER> /DEFAULTS=(FLAG, TRAILER, FORM=LTR_12)-
_MSA$MANAGER> /FONTS=MSAP$FONTLIST_APPLE35.TXT
MSA$MANAGER> EXIT
```

StyleWriter and ImageWriter: Printer Modes

I'm using TrueType, a StyleWriter and an ImageWriter. I upgraded to System Software 6.0.7, then to System 7.0. Both printers only work in BEST mode (not in the Draft or Fast mode).

Could this be due to the outline font technology (instead of bitmap)?

This article has been archived and is no longer updated by Apple.
The use of the effect of the "outlined" font has nothing to do with the disabling some of the print quality button selection.

Your problem is probably caused by how the application deals with the printer driver. Often when the application run into an unfamiliar printer driver, it will use the low level printer driver call, SetRsl to set printer resolution to the maximum. If this is done when using the StyleWriter, the "faster mode" push button will be disabled.

Applications like MacWrite, that talks only to the high level print driver, do not have this problem.

Final Cut Pro 3: OMF Exports Exhibit One Frame Offset in Pro Tools

OMF exports can result in Digidesign Pro Tools reporting a one-frame offset between audio and video tracks.
This article has been archived and is no longer updated by Apple.

Symptom

Pro Tools indicates that audio and video tracks are one frame off.

Solution

Apple believes this issue is caused by a combination of factors within Pro Tools. First, in some cases audio and video tracks slip by one or two audio samples. One audio sample is only about 1/1600th of a frame (assuming 48 kHz audio), so this is almost never noticeable. The second issue has to do with Pro Tools mismatching audio samples and video frames so that the offset of one or two audio samples is reported as being off by an entire video frame. This is purely a timecode reporting error and does not affect the actual synchronization of audio and video clips within Pro Tools or Final Cut Pro.

Contact Digidesign for more information on this issue.

Important: Information about products not manufactured by Apple is provided for information purposes only, and does not constitute Apple's recommendation or endorsement. Please contact the vendor for additional information.

DAL: How It Accesses DB-2 Tables via VTAM or CICS

1) How does DAL access DB2 tables in the VTAM version and when using the CICS passthru program?

2) How does DAL implement "stored procedures" on the host?

3) Please explain how the DAL-APPC implementation works?

This article has been archived and is no longer updated by Apple.

1) DAL uses the standard "TSO to = specs batch DB2 interface" to communicate with DB2. Security is supported via standard RACROUTE calls. The VTAM server is a multi-user server that runs as a batch job (or a started task) and that has a VTAM API front-end that controls access. The user needs a valid ID and password, but does not log on to TSO. Instead the user issues a "logon applid(_____)" command to connect to the VTAM Server. With the CICS passthru, the user logs on to CICS and requests the CICS transaction which uses APPC (LU62) to connect to the VTAM front-end of the server. CICS can be at version 1.7 but the PUT for LU6.2 support must have been applied to allow DAL VTAM Server access (version 2.1, or better, of CICS includes this LU62 support).

2) Stored procedures are kept in the DAL.AUTOEXEC file that is installed with the Server. (Only two sample database connection procedures are shipped with the server.) You can create your own procedures and store them there for general use. See the Server Installation Guide for more detail on this issue.

3) APPC communication from the client to the VTAM server (as opposed to from CICS to the VTAM server) requires the Apple product SNA*ps and its APPC Gateway. This connection type will allow for faster data transfer because it is not using the LU2 protocols (3270 data streams) but instead the LU6.2 protocols (APPC). Only the direct access method ("?ogon applid(_____)") to the VTAM server supports this protocol. The CICS passthru requires 3270 protocols (since CICS requires them) and therefore is supported by all the current network connections that support TSO server access.

System 7: How to Have More Then One Trash Can

Article Change History

09/11/92 - REVIEWED
* For technical accuracy.

I have two monitors attached to my Macintosh. I'd like a trash can in each of them. Is this possible?

This article has been archived and is no longer updated by Apple.
Yes, System 7 lets you make aliases for your trash can -- as many as you like. Here's how:

1) In the finder, select the Trash icon.

2) Choose Make Alias from the File menu. A new icon appears, named "Trash alias"

3) If you like, rename the alias -- anything but "Trash" -- and drag it to the other screen.

If you drag, say, a document into the new trash icon, the document actually goes into the original Trash. The original Trash icon expands to indicate there's something in it (though your alias will not bulge).

If you decide you no longer want an extra trash can, drag it into (you guessed it!) the original Trash.

Macintosh LC: Third-Party Solution For Co-Processor

Is there any way to install a co-processor into a Macintosh LC?

This article has been archived and is no longer updated by Apple.
Apple does not have a co-processor option for the Macintosh LC. However, our information search, which included the Redgate Macintosh Registry on AppleLink, provided these third-party solutions:

- "DataLink LC" and "FastMath LC" from Applied Engineering
- "MacCon+ series" from Asante Technologies
- "DaynaPort E/LC" from Dayna Communications
- "Apex" from Second Wave
- "QuikMath/LC" from System Technology Corp.

To locate a vendor's address and phone numbers, use the vendor name as a search string.

HD Setup: Differences Between Version 2.0.1 and 2.0.3

I need to find out what the differences are between HD Setup 2.0.1, 2.0.3 and the HD Setup for System 7.0B4.

I am especially interested in how initialization and bad sector mapping have changed and about reentrance code and where it resides on the drive.

This article has been archived and is no longer updated by Apple.
The differences between 2.0.1 and 2.0.3 were very minor minor bug fixes that never did crop up in normal use but the engineers knew they were there and fixed them anyway.

For the System 7 driver, it was modified to include a reentrant driver for support of virtual memory. The driver is written to the disk very early in the boot process to a portion of the drive to which we, as users, do not have access.

iMovie 3: Has Generic Icon and Won‘t Open After Reinstalling Mac OS X

iMovie 3 may have a generic icon and may not open if you reinstall Mac OS X.
This article has been archived and is no longer updated by Apple.

Symptom

iMovie does not open. Its icon looks like a generic application.

Solution

Use one of these solutions:

- Drag the iMovie application to the Trash, and use the Mac OS X installer to reinstall iMovie 3.

  or
- Install iMovie 3 separately. It can be installed from the iLife CD, or downloaded from the iMovie website (http://www.apple.com/imovie/).

Apple Does Not Release ELF Radiation Information

How can I get ELF radiation information on Apple products?
This article has been archived and is no longer updated by Apple.
Currently, it is Apple policy not to release this information unless there are extenuating circumstances (eg. a large bid on hold until ratings can be released under non-disclosure.) To date, ELF specific information has not been released to any customers.

At this time there is no standard for measuring and reporting VLF/ELF emissions. Without standards the numbers are meaningless unless they are compared only with other monitors measured in the same manner. Apple is using a Combinova¿ meter for measuring EMI, and a Radians-inova¿ meter for measuring ELF/VLF. The results of this testing are kept within the engineering group. Apple is taking the ELF/VLF issue seriously and is promoting significant research to study it.

Apple ensures that all of its products meet government regulations for the countries in which they are sold. A great deal of time and energy is being focused on the reduction of ELF/VLF emissions from our products, but at this time no product announcements have been made. Apple's official policy is that ELF/VLF emissions do not appear to pose a threat, and that additional studies need to be done.

Relatively low cost test instruments are available for those who wish to do their own comparison testing. Holaday Industries, Inc. sells test equipment which will meausure ELF/VLF emmissions. In addition, they offer occasional seminars covering various aspects of VDT emissions related issues. For more information, search under "Holaday Industries".

512K SIMMs: Work Only in Macintosh IIci and Macintosh IIsi

Can the 512K SIMMs that come in the 3MB Macintosh IIsi be used in any other Macintosh?

This article has been archived and is no longer updated by Apple.

512K SIMMs will ONLY work in the Macintosh IIci and Macintosh IIsi. They will not work in any other Macintosh.

Published Date: Feb 18, 2012

System 6.0.7: Compatible With Entire Macintosh Family

I have a hard drive which I would like to be able to connect to any Macintosh, from a Macintosh Plus to a Macintosh IIfx.

Will the lower-end Macintoshes operate if the hard drive is using System 6.0.7?

This article has been archived and is no longer updated by Apple.
System 6.0.7 is compatible all the way down to the Macintosh Plus; the only real requirements are 1MB of RAM and 800K disk drives. Your hard drive should work fine.

The one thing to remember is that you do not want to use this external hard drive you will be carrying around as the startup drive, because the installer scripts for each machine is different. In other words, you need to set up the system software for a particular machine. This would cause a problem if you used the hard drive as the startup drive on different model macintoshes. The only exception would be if the machine you connect it to is set up with the same installer scripts as the hard drives system software.

System 6.0.7: Troubleshooting Font Loading Problems

I'm having a problem with the Font/DA Mover on several networked Macintosh computers running System 6.0.7. Only one computer will load some PostScript Fonts. Other machines either lock up or have systems errors.

This article has been archived and is no longer updated by Apple.
Make sure that you are using at least version 3.8 of the utility. You mentioned PostScript fonts, but Font/DA Mover only moves bit images. It is possible that older bit fonts have a problem with the latest Font/DA Mover. These fonts would be fonts that don't include the FOND Resource.

If that is the case, you should open the suitcase containing these fonts and then save them to a new suitcase. This will create a FOND resource for them. Then copy these fonts to the System file.

Published Date: Feb 18, 2012

TrueType: Using With Non-Apple Printer

I have a Macintosh Classic running System 6.0.7 and an NEC SilentWriter 290 PostScript laser printer. I would like to use TrueType fonts for better screen display of text.

Can the TrueType fonts be used with the NEC printer, and what would have to be loaded onto the Macintosh Classic?

This article has been archived and is no longer updated by Apple.
TrueType is compatible with any output device as it is a self-contained driver and font set. Since you are running System 6.0.7, you have to install the TrueType INIT, and the specific TrueType fonts you wish to use. System 7 has the functionality of TrueType built in, so those running System 7 do not have to install the INIT, just the specific fonts they wish to use.

The INIT is available on the StyleWriter and Personal LaserWriter LS diskettes, or through authorized Apple resellers.

A/UX 3.0: "Root File System Is Full" Error Workaround (3/95)

I think I overfilled one of the drives with data; when I enter any A/UX command, I get "Cannot execute this command. The root file system is full".

I have tried cancelling when booting A/UX, but I still cannot execute any commands, even from that shell. Is there any way to get in and erase some files in my root file system?

This article has been archived and is no longer updated by Apple.
Interrupting A/UX from booting will bring you to the "A/UX Startup" mode or what is called SASH (Standalone Shell). You should get a startup# prompt.

Under startup#, try a "fsck" (file system check and repair) or a "rm" (remove a file).

If neither of these works, try the "chroot" (change root) command to change the current working root directory to a different one, like "Eschatology 1". To change the current working root directory to "Eschatology 1", do the following (where X is the SCSI ID of the A/UX boot drive):

startup# pname -cX -s3 "Eschatology 1"
startup# chroot (X,0,3)/

startup# rm (X,0,0)/FILES-ON-THE-DEFAULT-ROOT-TO-BE-REMOVED

After removing all the files you need, you can change back to the default root directory by issuing the command

"chroot (0,0,0)/"

Make sure do "fsck" on the default root filesystem to get a "clean" root file system.

A/UX: Questions About "Alerts" (8/94)

1. How do A/UX alerts work? If I am using a Macintosh or hybrid application, when an alert appears, can I switch to another process and/or Mac application?

2. If the process has a fatal system error when running A/UX, do I have to restart the Macintosh or only the process itself? How about a system bomb when running a Mac Application?

This article has been archived and is no longer updated by Apple.
1. You do have to deal with the alert in A/UX before switching to another process. This is the same as modal dialogs under the Macintosh operating system.

2. This is also similar to the Mac OS: it depends on "how fatal" the error is. Some errors, such as Out Of Memory conditions, only affect the active application. Other errors will trash significant portions of A/UX and freeze the system (this is what a Macintosh application will do if it bombs); others may disable the OS, but allow you to gracefully exit the other processes. There are really too many variables to predict exactly what will happen.

AppleShare: View By Icon Folders can‘t be Changed by Users

Is there any way to keep the folders and/or documents contained on an AppleShare File Server in a set order when viewed by icon? I have a 160MB File Server that has about 40 folders in it. Users are complaining that every time they connect to the server, they can't find a folder where they put it last.

This article has been archived and is no longer updated by Apple.
The actual views that an individual server user sees can be modified by the user but they will revert to the layout that the server administrator set up.

If the users can agree on a set organization of the folders, boot the server with a diskette and rearrange the folders then restart the server.

This is the only way for the folders to stay arranged in such a way as each user wants.

AppleShare: Can‘t Have A "Wild Card" Volume Name

I have a series of Macintosh Laboratories that are set up to use a single, "Campus Standard Startup disk". This disk is a floppy that students can take to any lab on campus, insert into a Macintosh, turn on the machine and have the server volume come up automatically.

All the servers have the name "Server" and there is an "*" in the AppleShare Prep file that I am told tells the Macintosh to look for the server in "the zone you are in". In the past, when a new lab has been brought up, we have just added the new server volume name to a list in the prep file. This is not working any more.

Is there any way we can get the format of the AppleShare Prep file? Or is there a way we can use the "*" to tell it to mount "whatever volume is on that server" like the "*" for zones?

This article has been archived and is no longer updated by Apple.
It is not possible to use a wild card for the volume name. It would appear that you are changing something in the AppleShare Prep file that is being ignored.

This is the "includes" definition for the Boot Mount List (BMLS resource).

```
bmlFSElSize EQU 0 ; size of this FSElement
bmlFSNumVols EQU bmlFSElSize+2 ; number of volumes for this
FSElement
bmlUAM EQU bmlFSNumVols+2 ; UAM chosen value (1,2,3)
bmlFSSTStamp EQU bmlUAM+2 ; server timestamp
bmlHasPassword EQU bmlFSSTStamp+4 ; if zero then no password saved
bmlFSPassword EQU bmlHasPassword+2 ; server password
bmlFSUName EQU bmlFSPassword+8 ; start of user name string
bmlFSSObjName EQU bmlFSUName+32 ; server NBP object name
bmlFSSZoneName EQU bmlFSSObjName+33 ; server NBP zone name
bmlFSVolInfo EQU bmlFSSZoneName+33 ; start of volume info
```

Xserve, Xserve (Slot Load): 180 GB Apple Drive Module May Have Incorrect Label

The antistatic shipping bags for small number of 180 GB Apple Drive Modules (ADMs) have a inaccurate label that states: "This drive is for use in an Xserve RAID only. Server Monitor software will not support this drive is installed in an Xserve."
This article has been archived and is no longer updated by Apple.

Symptom

An 180 GB ADM's antistatic bag label may inaccurately state: "This drive is for use in an Xserve RAID only. Server Monitor software will not support this drive is installed in an Xserve."

Solution

The 180 GB ADM is fully functional in Xserve and Xserve (Slot Load) servers. The statement on the antistatic bag label is incorrect and not a cause for concern.

Display Card 824 GC: Accelerates Any QuickDraw Application

Does the Macintosh Display Card 8*24 GC automatically accelerate ALL graphics, or is it necessary for a particular program to access the acceleration capabilities of the card to have any effect?

This article has been archived and is no longer updated by Apple.
The Macintosh Display Card 8*24 GC will accelerate any application that uses QuickDraw correctly.

The only reported application that the card won't accelerate is MacX. As of June, 1992 MacX has not yet been updated to make it compatible with the 8*24 GC's acceleration software.

Macintosh Display Card 824 GC: What SIMMs To Use

Can the 1MB 100ns SIMMs installed in a Macintosh II be used as memory on the Macintosh Display Card 8*24 GC? What about Macintosh IIfx SIMMs?

What are the specifications for SIMMS that work with the Macintosh Display Card 8*24 GC?

This article has been archived and is no longer updated by Apple.
No, Macintosh II or Macintosh IIfx SIMMs will not work.

The main specs are: 1MB, 256K ICs, 64-pin SIMM, 100ns. Use the Macintosh Display Card DRAM Expansion Kit (part number M0505LL/A) to upgrade the card.

There are other specs that are required that we don't publish (we provide it to RAM distributors). You will need to contact the third-party RAM manufacturers and simply ask for SIMMs that will work with the Macintosh Display Card 8*24 GC.

Macintosh Portable: Don‘t Ignore Battery Icon

How can I remove the battery icon that appears in the upper right hand corner of my Macintosh Portable screen? It interferes with "Balloon" Help and my SuperClock. I can't seem to find a way of controlling its presence in the menu bar.

This article has been archived and is no longer updated by Apple.
One reason for the icon's appearance is running the battery desk accessory; the Application Menu icon will show the DA's battery icon (in the top right corner).

Another possibility is that the battery is low, and the battery DA is flashing its icon as a notification to recharge.

Before you try to suppress it, it's important to know whether it's telling you something important.

MacTCP: Host File‘s 7K Storage Limit

Only about the first 118 lines of my Hosts file is being read when I press the "Host" button in the "Edit Command" box of MacX. Any items beyond line 118 bring up the message: "that Host cannot be translated", and they do not show up in the list window despite the fact that they are in the Hosts file.

Is there a limit as to how big the Hosts file can be, or can I change a setting to use a larger file? My host file is currently 484 lines.

This article has been archived and is no longer updated by Apple.
Yes, it is a known limitation on MacTCP Hosts file (and was stated in the Release Notes of MacTCP 1.0) that there is a 7K of storage limitation of parsing Hosts file.

The only workaround we can suggest is to use DNR (Domain Name Resolver) in MacTCP. This will reduce the size of the Hosts file.

Macintosh IIsi: When 8-Bit Color Is Missing

I have a Macintosh IIsi and 12-inch monitor. I see only four or 16 colors as selections in the control panel under monitors--but I should have 8-bit color. What is happening here?

This article has been archived and is no longer updated by Apple.

Here are a few suggestions that might cure your problem:

- Open the Monitors control panel. Click on the Options button. In the dialog box which appears, you can set aside more RAM for displaying colors. Click the button marked: "Up to 256 Colors/Grays" Click the OK button to return to the Monitors control panel.

- Reset PRAM. Under System 6.0.x, hold down the Command-Option-Shift keys while selecting the control panel. Click OK. Under System 7.x and Mac OS 8, hold down the Command, Option, P and R keys while starting up your Macintosh. When the Macintosh restarts again, release the keys.

- Restart from a System Tools Disk. If you can then select 8-bit color, trash and then reinstall the System Folder on the hard drive.

- If the above options don't work for you, you may have a problem with the Macintosh IIsi Logic Board.

TA47061_LaserWriter_Serial_Printing_from_MicroChannel_System_(TIL08657).pdf

LaserWriter: Serial Printing from MicroChannel System

I have a MiniMicro 386 with a microchannel bus. I'm in a Macintosh environment and want to print to the LaserWriter IINT.

I bought a Radio Shack cable 9- to 25-pin with transmit and receive reversed. I put the LaserWriter IINT into Diablo 630 Emulation Mode. When I tried to print, signals were sent to the printer but all that came out was a blank sheet. I then used a straight-through RS-232 cable with a null modem and got the same results.

Any suggestions?

This article has been archived and is no longer updated by Apple.
The problem printing serially could be caused by a number of things, but a straight-through cable with a null modem at the LaserWriter end should provide a workable solution.

However, you also need to make a couple of Mode Command statements to direct the output correctly to the LaserWriter. The commands are:

Mode: LPT1 96,N,8,1,P
Mode: LPT1 = COM1

System 6.0.7 Installer: Problem with TrueType

The System 6.0.7 Installer seems to have trouble dealing with reinstalling the System software onto a disk that is using TrueType.

Even when the Installer is just doing a simple installation, it compares the Backgrounder that it has with the one that's been installed, and refuses to continue unless it's given permission to replace the newer Backgrounder with the older one.

Is there a solution to this problem that DOESN'T require extreme acrobatics? Or will I have to install the System software, replacing the new files with the old, then reinstall the TrueType set?

This article has been archived and is no longer updated by Apple.
Unfortunately, here is no way around this situation. The System Software 6.0.7 Installer was released many months before the StyleWriter and Personal LaserWriter LS were introduced. The installer script writers did not anticipate this situation.

Published Date: Feb 18, 2012

System 6.0.7: EtherTalk, CD-ROM Driver Installation

I have a Macintosh IIsi with a CD-ROM and Ethernet Board. I need drivers for using both of these devices with System 6.0.7 and Installer 3.0 or greater.

This article has been archived and is no longer updated by Apple.
The Installer required to install the EtherTalk drivers are located on the Network Products Installer Disk, which is located in the "Read Me First" manual that came with the Macintosh IIsi.

There isn't an updated installer for the CD-ROM drivers, but there is a workaround. Just drag the following files into the System Folder:
- Apple CD-ROM
- Foreign File Access
- Audio Access
- CD Remote INIT
- ISO 9660 File Access
- High Sierra File Access

Use Font/DA Mover to install the CD Remote desk accessory, then restart the system.

AppleShare: Systems after 6.0.3 Need Network Products Installer

Is there any way to get AppleShare Installer with System 6.0.5? Can I just make a set of disks with System 6.0.5?

This article has been archived and is no longer updated by Apple.
It's not possible to upgrade the AppleShare Installer to System 6.0.5; disastrous things could happen if you tried the upgrade and then attempted an installation. The AppleShare Admin disk can be upgraded to System 6.0.5, as the application itself doesn't depend on the system version.

If you need to install AppleShare software onto a computer that requires a higher version of the System than 6.0.3 (like a Macintosh IIci or Macintosh IIfx), then you need to use the Network Products Installer Diskette to install the software. This disk is shipped with the computer (not the operating system) and can be found in the "Read Me First" booklet, which is inside the "Open Me First" box.

LocalTalk: Additional Cable Grounding Not Needed

I'm connecting my Macintosh networks with shielded twisted-pair cable.
What is the best way to ground this cable?

This article has been archived and is no longer updated by Apple.
There's no need to provide any additional grounding for LocalTalk cabling.
The shield is already grounded to chassis.

Published Date: Feb 18, 2012

ImageWriter I: Troubleshooting with Macintosh Classic (2/96)

I cannot get my Macintosh Classic to work with my ImageWriter I.

This article has been archived and is no longer updated by Apple.

Step 1

Make sure that the ImageWriter I printer's switch settings are

correct:

Switch 1

1-Off

2-Off

3-Off

4-Off

5-Off

6-On

7-Off

8-Off

Switch 2

1-ON

2-ON

3-OFF

4-XX

Step 2

Verify that you are using the correct cable. Cable part number 590-0555, or the original Macintosh to ImageWriter DB-9 to DB-25 cable (part # 590-0169) with the DB-9 to Mini DIN 8 Macintosh Peripheral Adapter cable (part # 590-0553) can be used.

Step 3

From the Chooser, verify the following:

- ImageWriter driver is selected

- AppleTalk is off

- The correct port is selected

If this does not work, you may want to start looking for hardware failures:

Try the ImageWriter on another computer, then try another printer with your computer.

DART: Utility for Duplicating Floppy Disks

Is there a Macintosh utility program for duplicating Macintosh, Lisa, Apple II or MS-DOS 3.5-inch floppy disks?
This article has been archived and is no longer updated by Apple.
DART (Disk Archive/Retrieval Tool) is an application that enables you to duplicate Macintosh, Lisa, Apple II, or MS-DOS disks, save disk images, and create disks from image files. DART 1.5 can read disk image files in DART, DiskMaker, or Disk Copy format. DART 1.5 image files are compressed, approaching a reduction in size comparable to that obtained by using a commercial compression utility. DART 1.5 is System 7.0 "savvy", and implements a custom Apple event mechanism to automate the conversion of older DART or Disk Copy files to 1.5 format. The conversion process can be run by "remote control" (even across a network!) using an accompanying HyperCard stack.
(For more information, please refer to the DART User Manual.)

Features of DART 1.5
---
* Data compression: more disk images can be archived in the same amount of space.
* Data checksumming for reliable disk duplication.
* Can read Disk Copy image files.
* Requires only 224K of RAM to run.
* Stack utility enables you to batch-convert DART 1.4 or Disk Copy files.
* Apple events support ("required" AE suite and custom 'cnvt' event.)
* System 7 "drag-and-drop" disk image creation.
* 32-bit clean.
* A/UX compatible.
* Color icons and balloon help.

Where to Obtain DART

As of December 22, 1997 DART is no longer supported.

Note: If you need to access disk images created by DART, you can use Disk Copy 6.1 or later.

Apple IIe: Best Way to Shut Down with Floppy Drive

Which of these is the better way to shut down an Apple IIe with a floppy disk drive?

1) Save the work
2) Wait until the in-use light is off
3) Remove the disk(s) from the drive(s)
4) Switch off the power

Or

1) Save the work
2) Wait until the in-use light is off
3) Switch off the power
4) Remove the disk(s) from the drive(s)

This article has been archived and is no longer updated by Apple.
Both methods of shutting down will work without any problems most of the time. The safest procedure is to remove the disk before shutting down. You should do that just in case there is some freak signal sent through the drive that corrupts the diskette. This is very rare but does happen.

iPod (Click Wheel) has long sync times or freezes with some PC FireWire connections

Is your iPod transferring music or data slowly when you connect it to your PC using FireWire? Keep reading to get your iPod into the fast lane!
This article has been archived and is no longer updated by Apple.
If you notice your iPod (Click Wheel) taking a long time to sync music or data, or even freezing if it's in Disk Mode, check what kind of FireWire bus host controller or onboard controller you have on your PC.

You can check this by using the Device Manager. To get to Device Manager:

1. Right-click on My Computer and select Manage.
2. Choose Device or Device Manager.

Under IEEE 1394 Bus host controllers, if it says VIA, you have a VIA chipset.

If your computer has a VIA chipset FireWire connection and a USB 2.0 connection, the USB 2.0 connection may provide a faster throughput for data transfer. You can try the USB 2.0 port if you have one or you can download the most recent iPod software update which addresses this issue.

Pascal : STRING and CHAR concatenation

This article has been archived and is no longer updated by Apple.

To concatenate using STRING types and CHAR types and not get a type mismatch error, use the routine below to create a STRING containing the CHARacters the user wishes to add to the STRING, then use the Pascal CONCAT to put them together. Make sure that if this is done within a PROCEDURE or FUNCTION, and the STRING is passed as a parameter, that the (*$V-*) option is used as well as declaring a TYPE to pass rather than STRING.

```
TYPE STR_TO_PASS = STRING;

PROCEDURE WHATEVER (ST : STR_TO_PASS);
BEGIN
END;
```

here's the concat stuff...

```
PROGRAM CONCAT_CHAR;

CONST LEN = 4; { or whatever you want }

VAR TEST_STRING : STRING;
CH : CHAR;
I : INTEGER;

(*$R-*) { turn Range Checking off so you can }
{ alter individual cells of the string }
BEGIN
TEST_STRING[0] := CHR(LEN); { set length of string }
FOR I := 1 TO LEN DO
BEGIN
READ (CH);
TEST_STRING[I] := CH;
END;
WRITELN;
WRITELN (TEST_STRING);
END.
```

Apple IIGS: Compatible Toshiba RAM

What Toshiba RAM chips are compatible with the Apple IIGS memory expansion board?

This article has been archived and is no longer updated by Apple.
The only Toshiba chip that we know of to be compatible are part number TMM41256P-15. The chips that are used in the Apple IIGS have to be 150ns, 256K x 1 bit, and CAS before RAS.

Apple II Plus: Monitor and Drives Compatible with Apple IIe

Can I use the monitor and disk drives from an Apple II Plus with an Apple IIe?

This article has been archived and is no longer updated by Apple.

Yes, it's okay to switch the monitor and drives between the two systems.

Published Date: Feb 18, 2012

Macintosh IIsi: Using with VGA Monitors (8/93)

I want to connect a Macintosh IIsi to a Sony CPD-1304 monitor. I've seen several references to the Macintosh LC and Macintosh LC II being used with VGA monitors, but nothing about the Macintosh IIsi.

This article has been archived and is no longer updated by Apple.
Most newer Macintosh models with built-in video support VGA monitors. The Macintosh IIsi, however, requires an adapter before it will support VGA.

Lapis Technologies, Inc. produces a DisplayServer card for the Macintosh IIsi that supports VGA output.

To locate a vendor's address and phone numbers, use the vendor name as a search string.

Article Change History:
6 August 1993 - Removed references to other models with built-in video.

Macintosh IIsi: Upgrading from 3MB Configuration

How is the Macintosh IIsi 3/40 configured so it has 3MB of RAM?

Also, do the four memory slots have to be full in order for the Macintosh IIsi to operate?

This article has been archived and is no longer updated by Apple.
The Macintosh IIsi has 1MB on the logic board and four 512K SIMMs installed to give a 3MB configuration.

As in all Macintosh computers, all slots of a particular SIMM bank must be filled for the machine to work properly. In the case of the Macintosh IIsi, all four slots must be filled.

Apple Hard Drives: Moving Internal To External

Do you know of any way to turn internal hard drives into external hard drives?
This article has been archived and is no longer updated by Apple.
The mechanisms are no different, but here is what you will need to go through to be able to do it. Is is probably more trouble than it's worth.

- You will need to obtain an external hard drive case
- You will need to obtain a power supply for the external case
- You will need to obtain a different mounting bracket
- You will need to obtain an external SCSI cable and termintor

This is not an easy process, and probably not cost effective when including labor costs.

AppleScan: Can‘t Run from Read-only Server

I'm trying to set up a scanner operation to work remotely. How can I keep AppleScan on a read-only server and make it accessible to those logging on from a scanner at a remote site? (Both are running System 7.)

AppleScan is being "shared" from a Macintosh with "read only" status. Unfortunately, AppleScan needs to write a file when it is launched. An alias doesn't seem to work, because it still launches from the server.

This article has been archived and is no longer updated by Apple.
Because AppleScan creates temporary work files in the folder where it is located, there is no way to make it work in a "read-only" situation. The application would need to be re-written with read-only file server operation in mind. The temporary files would need to be written to another location that is not read-only. In AppleScan, there is no method for designating where the temporary files will be written.

An alias does nothing to improve the situation because it simply points to the original application.

Two possible workarounds:

- Download the application from the server to the remote site and then execute the application at the remote site.

- Place the AppleScan software in a read-write location on the server.

System 7: Function of Backgrounder File

What is the function of Backgrounder (on the System 7 Printing disk)? There's no Backgrounder on my hard disk, yet I can print to a LaserWriter IINTX successfully in the background.
This article has been archived and is no longer updated by Apple.
In System 7, the function of the Backgrounder is built into the Finder. You don't need the Backgrounder file at all if you're running System 7.

The Backgrounder file is, however, required on System 6.0.x systems that use System 7 printer drivers if they are to do background printing.

When you run the Installer on the 7.0 Printing Tools Disk from a 6.0.x system, the Backgrounder on that disk is installed on the 6.0.x system.

Applesoft Reference Manual: Errata

Listed below are corrections to the Applesoft Reference manual.
This article has been archived and is no longer updated by Apple.
Page 5
Paragraph 4, the last line should read: However, only the first 9 digits are usually significant, and the tenth digit is rounded off.

Page 15
Line 90 should read: 90 DIM A(8): REM DIMENSION ARRAY WITH MAX. 9 ELEMENTS

Page 15
Line 180 should read: 180 IF A(I) <= A(I+1) THEN GOTO 240

Page 21
The line about mid-page that reads
C$ = RIGHT$(B$,3) + "-" + LEFT$(B$,4) + "-" + MID$(B$,6,7) should read
C$ = RIGHT$(B$,4) + "-" + LEFT$(B$,4) + "-" + MID$(B$,6,7)

Page 23
Line 180 should read: 180 I = I+1: IF I < 15 THEN GOTO 130

Page 51
If TAB(X) is the last item in a PRINT statement Applesoft will act as if there is a semi-colon after it.

Page 52
If SPC(X) is the last item in a PRINT statement Applesoft will act as if there is a semi-colon after it.

Page 53
FRE returns the amount of memory ... Applesoft sometimes stores duplicate strings separately.

Page 53
PRINT FRE (0) sometimes returns a negative number because of the way integers are handled in Applesoft. Adding 65536 to the negative number will give the positive representation.

Page 63
Rule 2 should read "The total number of elements RECALLed must be at least equal to" instead of "...equal th".

Page 66
Similarly, a response... If an ASCII NUL character, CTRL-SHIFT-P, is included in a line of input, the input will be truncated at the character before the NUL. A NUL as the first character in response to INPUT A$ will result in a null string. A NUL as the first character in response to INPUT A will result in ?REENTER.

Page 66-67
A line of input longer than 255 characters will be cancelled by the monitor and the user is left in the input statement. A line greater than 239 but less than 255 will be truncated to 239 characters.

Page 81
ONERR GOTO, "When an error occurs..." should read "After executing an ONERR GOTO command, when an error occurs...".

Page 96
Paragraph 1, line 6, the sentence that starts "Press the RESET key..." should read "Type CALL -151" because Apple IIs with the Auto-Start ROM will not go into the monitor when the RESET key is pressed.

Page 102
The function for LOG of X base 10 is LOG (X) / LOG (10).

Page 118
"1) Use multiple statements" states that the maximum line number is 65529 when the actual maximum line number is 63999.

Page 131
Second paragraph, line 7, replace "POKE 22,W" with "POKE 33,W".

Page 135
Replace the top part with:

260 POKE -16296,0
Clear game control "annunicator" output #0 (Game I/O connector, pin 15) to TTL low (0.3 volts). This is the "off" condition: maximum current 8 milliamperes.

270 POKE -16295,0
Set game control "annunicator" output #0 (Game I/O connector, pin 15) to TTL high (3.5 volts). This is the "on" condition: maximum current 0.4 milliamperes.

280 POKE -16294,0
Clear game control "annunicator" output #1 (Game I/O connector, pin 14) to TTL low (0.3 volts). This is the "off" condition: maximum current 8 milliamperes.

290 POKE -16293,0
Set game control "annunicator" output #1 (Game I/O connector, pin 14) to TTL high (3.5 volts). This is the "on" condition: maximum current 0.4 milliamperes.

300 POKE -16292,0
Clear game control "annunicator" output #2 (Game I/O connector, pin 13) to TTL low (0.3 volts). This is the "off" condition: maximum current 8 milliamperes.

310 POKE -16291,0
Set game control "annunicator" output #2 (Game I/O connector, pin 13) to TTL high (3.5 volts). This is the "on" condition: maximum current 0.4 milliamperes.

320 POKE -16290,0
Clear game control "annunicator" output #3 (Game I/O connector, pin 12) to TTL low (0.3 volts). This is the "off" condition: maximum current 8 milliamperes.

330 POKE -16289,0
Set game control "annunicator" output #3 (Game I/O connector, pin 12) to TTL high (3.5 volts). This is the "on" condition: maximum current 0.4 milliamperes.

NuBus: Recommended Board Placement for 24-bit Mode

I've heard that the placement of NuBus boards in Macintosh IIci and IIcx computers can affect memory use and performance under System 7. Is it true that the boards should be placed contiguously from left to right in Macintosh IIcx computers, and from right to left in Macintosh IIci computers, to maximize memory performance?

This article has been archived and is no longer updated by Apple.

RECOMMENDATIONS

Yes, there are recommendations as to where the NuBus cards should be placed. This has to do with heap fragmentation, not speed.

The following recommendations are valid only for 24-bit mode:

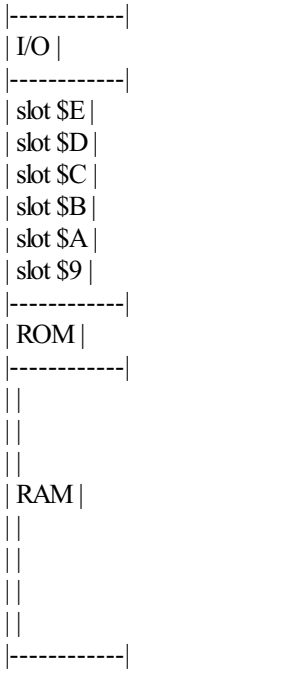
- The Macintosh IIcx should have the cards placed from left to right.

- The Macintosh IIci should have the cards placed from right to left.

- Any Macintosh with six slots should have the cards placed contiguously from either side.

BACKGROUND

The memory map of any Macintosh running in 24-bit mode is 8MB for RAM, 1MB for ROM, 6MB for slot space, and 1MB for I/O. This is in order from bottom to top as follows:

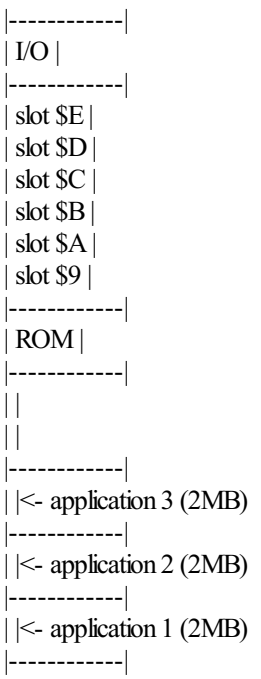


There may be more memory than the amount that shows up as the largest unused block, and thus the amount available for an application to be loaded into, because the memory is fragmented. Say, for example, you had a Macintosh IIfx set for 13MB with virtual memory, with a card in slot $C. Applications were then loaded one after the other that took 7MB of memory combined. The largest unused block would be 3MB, even though there were 6MB of memory available to use, as only 3MB of it was contiguous. The 1MB below ROM, as well as the 2MB from slots $D and $E, could be used, but only as 1MB and 2MB chunks, respectively.

This is the same thing we see when multiple applications are launched, and then one of the middle applications is quit. The memory that the middle

application used is not added to the largest unused block.

In the example below, three applications, each using 2MB of memory are loaded. Assume for this example that virtual memory is not on. If you then quit from application 2, the largest unused block would be 2MB, even though 4MB is not being used. If you load another application that used 1MB of memory, you would have 2MB as the largest unused block, because the 2MB on top is still available. This is the same issue as with the NuBus slots and virtual memory. When a card is placed in a NuBus slot, it is the same as having an application permanently loaded in that space.



With that in mind, on a Macintosh IIcx, the NuBus slots used are $9, $A, and $B. Therefore, if you fill $9 first, which is right next to ROM, you have 5MB of contiguous slot address space. If you fill $A first, you have two chunks, one of 1MB of contiguous slot address space, and the other 4MB of contiguous slot address space, and thus 4MB would be the largest unused block.

A Macintosh IIci uses slot $B for video RAM. The NuBus slots used are $C, $D, and $E. If you are using built in video, it doesn't matter which way you load the cards. If you are not using built in video, using slot $E first would give you the most contiguous slot address space.

On a Macintosh with six NuBus slots, it does not matter which direction you fill the slots from, but to get the most contiguous space, they should be loaded one next to the other.

The ordering of the NuBus cards solely affects heap fragmentation. This has NO effect on the speed of virtual memory. Once you load the applications, the speed is the same regardless of where you place the cards. Heap fragmentation gives you less contiguous memory to load things in, but it does not affect the system's speed.

Remember, this is true only in 24-bit mode. Once you go to 32-bit addressing, the whole address map changes, and this is no longer an issue.

AppleWorks 3.0: How To Set Privileges on Network

With the network version of AppleWorks 3.0, how can privileges be set so AppleWorks users can not delete the program or necessary program files?

This article has been archived and is no longer updated by Apple.

If Aristotle is not in use, within AppleShare you can assign a printer to a particular user. You also have the option to select a printer from the Chooser or to type the name. If the name chosen or typed in does not match the spooled printer's name, the printer won't be seen. We suggest verifying what the name of the printer for each user is.

You can set the folder privileges so the users have read-only rights. Do not give users the ability to make changes.

Apple IIGS: "AppleTalk must be installed" Error

I am trying to print AppleWorks on a LaserWriter from an Apple IIGS over AppleTalk. I downloaded "Apple IIGS: Printing to the LaserWriter from AppleWorks" from Tech Info on AppleLink. When trying to set this up by going into the Chooser, I get the error message "Error: AppleTalk must be installed to run this program."

This article has been archived and is no longer updated by Apple.
The error message is a little misleading. The actual cause is an improper setting of the slots in the Apple IIGS Control Panel.

With the older Apple IIGS (256K of RAM on the logic board), you need to set Slot 1 to "Your Card" and Slot 7 to "Built-In AppleTalk". If you have a newer Apple IIGS (1MB RAM), set only Slot 1 to "AppleTalk". You'll have to restart after making the changes for them to take effect.

Aristotle: How To Exceed the 150 Application Limit

I'm working with Aristotle on an Apple IIGS school network and have 150 applications listed in our current menu. The Apple IIGS teacher workstation has 2MB of RAM installed.

I want to add additional applications to the network, but run up against the 150 limit. How can I create an additional menu while continuing to work under "Administrator"?

This article has been archived and is no longer updated by Apple.
The Aristotle user manual has a 256K RAM card/cache set for initial setup. By increasing the amount of RAM card/cache, you should be able to exceed the 150 barrier that you encountered. The Users, Teachers and menu information are loaded into the RAM card/cache when you log on to the server.

Macintosh: "Bad F-line Instruction" Error

I am getting a "Bad F-line Instruction" errors on my 68k Macintosh computer. What causes these errors?
This article has been archived and is no longer updated by Apple.
In System 7.x, the "Bad F-line Instruction" error is also referred to as the "Co-processor Not Installed" or "No FPU Installed" error; in System 6.0.7 it is referred to as the ID=10 error.

F-Line instructions are used to access attached processors, such as a floating-point math co-processor. A bad F-Line instruction is a bad Floating Point Unit (FPU) call. However, when you see this on computers without FPUs, or in applications that do not support an FPU, then it is probably a spurious error. These messages often indicate software related errors generated by a program that has extraneous program code. On very rare occasions a hardware failure generates these errors.

With System 6.0.7, these errors do not have a direct relationship with floating point co-processors; you will not resolve this error by installing an FPU. In System 7.x, there may be a problem with the math chip, or it may be an unrelated software error.

The error may be caused by bad code in the application which is calling a processor that is not present or calling a memory location that is not there. There may be a corrupted application or an extension causing some spurious memory problem.

A possible solution is to remove and reinstall the application and/or remove and reinstall the system software.

NOTE: On Power Macintosh computers, there may be additional causes to these types of errors. See the Tech Info articles, "Power Macintosh Computers: No FPU Installed Error" and "Power Macintosh: Type 11 & No FPU Errors Technote" for additional information.

Apple Writer IIe: DOS 3.3 Printer codes from all Apples

Many printers have special features that the computer signals by sending command codes.

To send codes to a printer from Apple Writer IIe under DOS 3.3, you must insert the codes into the Apple Writer file you want printed. The manual of the printer may list the codes by several names: decimal, hexadecimal, teletype abbreviations (SOH, ETX, DC1, DC3, etc.), standard keys, and combinations of the above.
This article has been archived and is no longer updated by Apple.
Using the chart "ASCII characters, values, and keystrokes", you have to translate from the name of the code in the printer manual into the name of the corresponding keystroke or keystrokes on the keyboard of the Apple IIe, Enhanced Apple IIe, or Apple IIc.

Some keystrokes put so-called control characters into the Apple Writer file. These control characters are not part of the conventional English character set; while screen shows them, the printer intercepts and does not print them, instead recognizing them as signals to turn special functions on and off or to change printer settings.

NOTE: In the descriptions of the keystrokes, the characters greater than and less than, < and >, are used to contain one keystroke, which can mean that:

1. You must simultaneously hold down the control key, the shift key, or both as you press the other key, or
2. You must press a special key, such as ESC or RETURN.

With these considerations in mind, here is a list of codes and methods for inserting them in an Apple Writer file.

Null (ASCII value 0):
The following patch is for Apple Writer IIe under DOS 3.3. The patch allows you to enter NULs (CTRL-@) when in CTRL-V mode. The only side-effect is that the DELETE key doesn't work for correcting a filename entered from the keyboard for the DOS COMMANDS or ADDITIONAL FUNCTIONS menu; instead, just use the left arrow key.

1. Boot the DOS 3.3 System Master diskette.

2. Remove the System Master diskette, insert the Apple Writer IIe under DOS 3.3 diskette and type the following commands.

```
BLOAD OBJ.APWRTIIE
CALL -151
1CE1:EA EA EA EA
3EBA:EA EA EA EA
3D0G
UNLOCK OBJ.APWRTIIE
BSAVE OBJ.APWRTIIE,A$1900,L$2F58
LOCK OBJ.APWRTIIE
BLOAD OBJ.APWRTIIF
CALL -151
1D81:EA EA EA EA
4033:EA EA EA EA
3D0G
UNLOCK OBJ.APWRTIIF
BSAVE OBJ.APWRTIIF,A$1900,L$30D1
LOCK OBJ.APWRTIIF
```

If you don't want to do this to your Apple Writer IIe diskette, refer below to the Applesoft BASIC solution.

Control-A through Control-Z (ASCII decimal values 01 through 26):

Example: Control-Z (ASCII decimal value 26): <CTRL-V><CTRL-Z><CTRL-V>

Exception: Control-V (ASCII decimal value 22) can't be entered. See "Missing Characters" below.

Escape (ASCII value 27): <CTRL-V><ESC><CTRL-V>

Other Control characters: These can be entered in the manner of Control-A through Control-Z.

Missing Characters:
You can't directly enter a Control-V in Apple Writer. To use these and other characters in Apple Writer, it is necessary to use an Apple Writer glossary file.

Apple Writer doesn't send a Null character.

Applesoft BASIC can be used to send a Null character to your printer by following these steps:

1. Create your Apple Writer document as usual, but substitute a unique character in each place that you want a Null character.

2. Type <CTRL-P> to display the Print/Programs Command menu.

3. Type PD8, Apple Writer's code for Print to Disk on an Apple II.

4. Type NP to begin printing.

5. To the Apple Writer prompt for a file name, do not enter the same name with which the file is already saved. Enter a unique name, and note it down.

6. After the printing to disk is finished, exit Apple Writer and boot up a ProDOS diskette.

7. Run the following program:

```
100 HOME
110 PRINT TAB(10);APPLE WRITER TO PRINTER"
120 VTAB 5
130 INPUT "NAME OF APPLE WRITER FILE PRINTED TO DISK: ";F$
140 IF F$="" THEN 900
145 VTAB 12
146 INPUT "CHARACTER TO REPLACE: ";X$
147 IF X$="" THEN 145
150 VTAB 10
160 INPUT "PRINTER SLOT #: ";S$
170 IF S$="" THEN 900
180 S=VAL$(S$); IF S < 1 OR S > 7 OR INT(S) <> S THEN 150
190 D$=CHR$(4)
200 ONERR GOTO 800
210 PRINT D$;"UNLOCK";F$
220 POKE 216,0
230 VTAB 12: PRINT SPC(75)
240 PRINT
250 PRINT D$;"PR#";S
260 PRINT CHR$(9);"132N"
270 PRINT D$;"OPEN";F$280 ONERR GOTO 400
290 PRINT D$;"READ";F$
300 A$=""
310 GET C$
315 IF C$=CHR$(12) THEN 310
320 IF C$=CHR$(13) THEN 350
330 IF C$=X$ THEN C$=CHR$(0)
340 A$=A$+C$:GOTO 310
350 PRINT A$
390 GOTO 300
400 POKE 216,0
410 PRINT D$;"CLOSE"
420 PRINT D$;"PR#0"
430 VTAB 15
440 PRINT TAB(5);"FILE ";F$;" HAS BEEN PRINTED."
450 GOTO 900
800 POKE 216,0
810 VTAB 12

Macintosh: Troubleshooting ID=01 "Bus Error"

I'm getting a lot of ID=01, "Bus Errors" on my Macintosh.

It has happened when I'm setting up disks (both floppies and external hard disks); it has happened with most of the programs I run; it has happened when I try to print. What does it mean?

This article has been archived and is no longer updated by Apple.
ID=01, or "Bus Error", is one of the more common System errors, along with 02, 03, 10, 25, 28. The main reason you are seeing this type of error is that the programmers have changed their coding of errors from an ID-XX format to a "more helpful" word-based error. A Bus or Coprocessor Error can be caused by any application (including the Finder) trying to access any memory address in the F hexadecimal range, which accounts for approximately 50% of the address ranges in most Macintosh models.

These errors usually represent some sort of software incompatibility. It could be that the application is incompatible with the System version, a system extension or INIT (screen dimmer, startup screens, startup sounds, etc.) is conflicting with another extension, or the extension is incompatible with the System version.

There are three ways to reduce the frequency of this error:

1) First try removing all third party extensions (INITs) and control panels from your System Folder, as there may be a potential conflict there. (If running System 7, holding down the Shift key as the Macintosh starts up accomplishes this for the current session.) After restarting, if the Bus Error ceases, the problem is with a conflicting extension or control panel, or perhaps a combination of them. Move these files back into the System Folder gradually, restarting between each move, until you identify the conflicting file.

2) Be sure the computer is free of ANY virus, but particularly the WDEF strain. System 6.0.7 has serious problems with WDEF, and in 90% of the cases we've seen these bus and coprocessor errors were caused by WDEF.

3) Throw away the current System Folder and reinstall from known good LOCKED disks.

Use your machine for a day or so before adding extensions or control panels back into the system to see if the same errors come up. If they come up only in certain applications, check with the software manufacturer to make sure you have the most current version, and whether they have seen or heard of the problems you are having.

There is a slight chance the errors are hardware related. If the software fixes don't work, try running diagnostics on the hardware. The following parts are the likeliest problem spots:

* RAM
* Logic board
* Hard drive

EtherTalk Installation: How System 6.0.7 and System 7 Differ

Will System 6.0.7 and System 7.x automatically install EtherTalk 2.0.2 as needed for a Macintosh IIfx?

This article has been archived and is no longer updated by Apple.

System 6.0.7

System 6.0.7 does not automatically install the EtherTalk Drivers. You must use the Network Products Installer that comes with the computer. This correctly installs the Network CDEV and network drivers.

System 7

System 7 automatically installs network drivers and CDEVs -- if a network card is installed on the computer. If you find that some networking software you need is not installed, use the Installer program on your System installation disks and use the Customize option. The Customize option lets you install the specific software you want without disturbing the rest of your system.

System 6: Non-Opening Folder May Be a Memory Problem 2/93

Article Change History

02/02/93 - REVISED
* To indicate that this is valid for System 6 only.

Is there a limit to the number of files that can be placed in a folder? I have over 1,000 files in a Data Club network folder, and it will no longer open.

This article has been archived and is no longer updated by Apple.
The maximum number of files and folders available on a hard drive is roughly limited to about 4.3 billion total, with a 64,000 file limit. If you're having a problem opening the files, it may be related to Finder memory allocation instead.

Do this:

1) Do Get Info on the Finder. (In the Finder, select the Finder file, then choose Get Info from the File menu.)

2) Increase the Application Memory Size by 100K.

3) If that doesn't work, increase the memory allocation by another 100K.

ImageWriter 15-Inch: How To Improve Blurry Printing

I have an ImageWriter 15-inch (wide carriage). When printing in "Best" mode the letters appear blurry.

When the printer puts down the second strike from the other direction during printing it is slightly off, giving the job a blurry look. (I have tried printing the same things with a narrow-carriage ImageWriter I and the print is much sharper.)

I've tried adjusting the carrier wire, replacing the logic board, drive transistor set, carrier motor, carrier wire, and print head, but none of these things helped.

Does the mechanical assembly just wear out after a time, producing a little "slop" that could cause this problem? Is there an adjustment for horizontal linearity? Is there a way to get unidirectional printing in the "BEST" mode?

This article has been archived and is no longer updated by Apple. Printers, like all mechanical devices, eventually exhibit symptoms of fatigue and general wear and tear. There is a point in every printer's life cycle where the cost to repair exceeds the cost of replacement.

Here's what you can do to help your ImageWriter 15-inch:

1) Perform the VR1 adjustment. This adjusts for optimum vertical alignment. This is more of a fine tuning adjustment but should be performed first.

2) Clean the Carriage Rails thoroughly. This means buff the rails and make sure they are clean all the way around. A quick wipe will not do the trick.

3) Check the carrier wire (Apple Part #970-0818) that attaches to the Carrier Assembly. Where the cable mounts to the carrier assembly, a small rubber bushing is used to isolate the Carriage assembly from the cable. As the printer ages, this rubber bushing may deteriorate. If that seems to be the case, order another bushing and see if that solves the problem.

Unidirectional printing in Best mode is not an available option.

LaserWriter II: 6MB Configuration Won‘t Cause Problems (11/94)

I've been told that a 6MB RAM configuration in a LaserWriter IIntx can cause problems.

The only documentation I've been able to locate states that the 6MB configuration can be physically installed, but that the printer will recognize only 5MB.

Will leaving excess memory in the otherwise empty slots cause any damage or problems with the printer or the attached systems?

This article has been archived and is no longer updated by Apple.
As you have discovered, 1MB of the 6MB is not be recognized. We are not aware of any problems that could be caused by having 6MB installed in the printer.

MacX: Uses Standard Macintosh System Color Palette as Default

When plotting a color bar of 256 colors in MacX, I get a full range of colors on the left side (colors 0 through 128 or so) but get only a solid color on the right (colors 128 to 256). When printed to a Tektronix color printer, the screen dump routine returns a error message "130 colors found". This occurs in both root and rootless windows.

The color bar is complete (256 colors) on both the screen and printer when running White Pine's Exodus II, and matches the color table of the host.

Why isn't MacX displaying all the colors like Exodus II?

This article has been archived and is no longer updated by Apple.
There are many X client applications that use the standard or default X color map. MacX uses the standard Macintosh system palette as the default color map (which it should), and this can lead to the situation you describe because the System palette has 128 colors locked in and no additional colors specified.

If the X client application requests a new color map from MacX, it should get the full 256 colors it requests.

TA47110_Apple_III_Problems_with_cursor_positioning_in_CPM_(TIL00872).pdf

Apple III: Problems with cursor positioning in CP/M

This article has been archived and is no longer updated by Apple.

If you're having problems with cursor positioning in CP/M--specifically, problems with accessing rows 8 or 9 from BASIC--you're probably using a version of CP/M earlier than version 2.21. The remedy is to upgrade to CP/M 2.21, and then to study page 32 of the documentation that comes with that upgrade.

Apple II: Mouse Memory Locations

What are the memory addresses for mouse information on the Apple IIe and Apple IIGS?

This article has been archived and is no longer updated by Apple.

Apple IIe/IIc

With the mouse card in slot four of the Apple IIe, locations are stored as follows:

- low byte x $047C

- high byte x $057C

- low byte y $04FC

- high byte y $05FC

(This is different if the card is in a slot other than slot four.)

More data on Apple IIe and IIc applications is on pages 196 through 198 and page 363 of the "Apple IIc Technical Reference Manual" from Addison-Wesley.

Apple IIGS

Information on the Apple IIGS locations is on pages 200 through 205 of the "Apple IIGS Firmware Reference" from Addison-Wesley.

MultiFinder: Application Memory Is Released at Quitting

Under MultiFinder or System 7, does the Memory Manager lock up memory allocated to an already launched application (reserving any extra RAM in that allocation for other calls to memory), or does the Memory Manager allow other programs to reuse allocated memory?

This article has been archived and is no longer updated by Apple.

The memory allocated to an application is reserved for that application when it is running. But when the application is quit, the reserved memory goes back into available memory for other applications to use.

SCSI: Apple Supports Both SCSI Group 0 and Group 1

I understand that computers that use SCSI Group 0 set of commands on drives larger than 1.073742 gigabytes will, when they reach the 1.073742 limit, wrap around to the beginning of the disk, overwriting the first blocks.

I am also told that the SCSI Group 0 set of commands is in some Sun Microsystems -- and virtually ALL Apple -- operating systems.

If this is true, what is the solution if I want to have these large capacity drives? Are the vendors of these large drives responsible for providing a solution?

This article has been archived and is no longer updated by Apple.

Apple's "driver" (software installed to the drive during HD SC Setup and uploaded to the memory during system boot) can be set up to use either 6 bytes (Group 0) or 10 bytes (Group 1) SCSI commands. Although they are using 6 bytes command currently, if the capacity of our drives goes beyond 1.2GB, then the driver can be changed to use Group 1 commands for those drives.

The Macintosh OS can allow different drivers to exist at the same time, so we don't have to change the driver for the current drives, just add the new driver when necessary. Incidentally, our current drives support both group 0 and group 1 commands, too.

Our driver currently supports Group 0, but can easily be modified to support Group 1 when necessary.

Note: Apple's driver only supports Apple hard drives. Third-party hard drives require their own drivers.

System 7.0: "Put Away" Problem Workaround

Article Change History

09/11/92 - REVISED
* To make more clear.

I'm having a problem with System 7 when I follow these steps:

1) Drag an application to the desktop.

2) Select it and use the Put Away command on it.

3) Close the window the Application is in. Now double-click on any document for that application.

4) A message says the application can't be found.

This article has been archived and is no longer updated by Apple.
Here's a workaround: Don't use Put Away. Instead, drag the application to the desktop again, then drag it back to fix the problem. Rebuild the Desktop file.

MacTCP: System 7 Compatibility Problems and Workaround

Is there a System 7-compatible version of MacTCP?

Since I've upgraded, I've lost my Ethernet connectivity and have to log on to the mainframe via Microphone II, which is very slow in a terminal emulating mode. I've also lost my FTP capabilities.

This article has been archived and is no longer updated by Apple.
Although currently (August, 1991) MacTCP is not fully compatible with System 7, you actually can use MacTCP -- if you put it in the right place.

Take MacTCP out of your Extension folder and put it into the System folder itself. Since you are making your connection via LocalTalk, and since you cannot be running VM, you should be able to make a connection.

This is a workaround, but it should give you the same functionality you used to have until full compatibility with System 7 is available.

TrueType: Combining Fonts Under Common Name in Font Menu

I want to combine TrueType family of typefaces into one common name under the Font menu: for example, typefaces like Times-bold & Times-italic appearing under one name (Times) in the Font menu.

I have heard of utilities that do this for PostScript fonts (Fifth Generation Systems', Inc. Suitcase II/Font Harmony being one) and also resolve ID conflicts with different fonts. Is there something similar for TrueType?
This article has been archived and is no longer updated by Apple.
The FOND resource is what makes it possible to have different styles of one font family show as one item in a font menu. The possible styles include plain and any combination of the following: bold, italic, underline, outline, shadow, condensed, and extended. Typically, the font styles you see are plain, bold, italic, and bold-italic. Sometimes you see a condensed font. This mechanism is not intended to combine AvantGard-Demi and AvanteGard- DemiOblique under the same font menu item.

Modifying a FOND resource to support more font styles is not something we recommend, as it is rather tricky. However, if you want to try, please read Macintosh Technical Note #198 and Inside Macintosh Volume IV, chapter 5, specifically page IV-39. These documents provide the information you need to attempt this.

We contacted Fifth Generation Systems, Inc., who told us their Font Harmony product does not currently support TrueType fonts.

AppleShare: Suggestions for Expanding Beyond 50 Users

I have 35 computers on my AppleShare network and need to add 20 workstations. I have a star controller. Do I need to divide the network into zones? Do I need to add a bridge? Do I need to add another file server?

This article has been archived and is no longer updated by Apple.
If you go over the 50-user limit, not everyone will be able to log on to your server at the same time and the network will slow down.

Another AppleShare file server is needed. We also suggest you add an Apple Internet Router that runs in the background on the servers. This will enable you to break up your network into logical zones. Each Internet Router supports two LocalTalk networks. You also might want to consider using an Ethernet backbone between the servers to speed things up.

Aristotle: Troubleshooting Menu Management "File Already Open."

I have an AppleShare network with Apple II workstations and a Macintosh file server. My problem is with Menu Management in Aristotle. After I make changes in menu.m and I try to save changes, I get the error "File already open." Even after repeated tries, I still get this error and must quit without saving my changes.

This article has been archived and is no longer updated by Apple.
The problem may be with the Access Privileges in the Administrator's ESP folder.

Aristotle's menu management program creates folders named ESP that are stored within individual users' folders on the server's startup volume. In order for Aristotle to work correctly, access privileges must be set up in a certain way:

1) Open AppleShare Admin.

2) Display the list of folders.

3) Open the Users folder.

4) Open the appropriate user's folder.

5) Display the access privileges on the ESP folder.

6) Ensure that all boxes in Access Privileges are checked EXCEPT "Make Changes: Everyone".

7) Make sure that Teacher appears in the Group box.

AppleWorks: Landscape Printing on LaserWriter Not Supported

I'm using a LaserWriter Plus with an Apple IIe and AppleWorks 2.1. I can print to the LaserWriter using either Diablo emulation or the IWEM ImageWriter emulator. (This is a stand-alone configuration, with the Apple IIe printing through a Super Serial Card.)

1) Can the Diablo emulation mode print sideways?

2) Can I change IWEM for landscape printing, or could AppleWorks be used to send a PostScript "setup string" to the LaserWriter to prepare it to print sideways?

This article has been archived and is no longer updated by Apple.
Landscape LaserWriter printing is not supported using Diablo 630 emulation, just as it is not feasible on a Daisy Wheel Printer. The daisy wheel would need another print head to handle the 90 degree rotation of print.

As far as altering the IWEM to print landscape, this is theoretically possible but we know of no easy way to do this. It would involve a fair amount of PostScript programming changes to the IWEM.

Macintosh: Troubleshooting Frequent Hard Disk Access Light

My hard drive access light comes on every 15 seconds or so, blinks as if it is accessing a file, then stops. This happens all the time. What's going on?

This article has been archived and is no longer updated by Apple.
This behavior is most likely caused by a third-party INIT or CDEV, such as On Location, rather than by a hardware problem. An easy test is to start up your system with a known-good System floppy disk. If the symptoms persist, then you may have a damaged hard drive -- though the problem is most likely in software.

Published Date: Feb 18, 2012

Macintosh Portable: Tips for Long-Term Storage

If I use my Macintosh Portable only once every three months, how should I treat the battery: do nothing or keep the charger attached?

This article has been archived and is no longer updated by Apple.
The Macintosh Portable battery is a sealed lead-acid battery and must be recharged periodically in order to maintain normal battery life. If the battery falls below 5.4 volts, it cannot be recharged.

To prevent the battery from completely discharging, keep it plugged in to the Battery Recharger, or leave the Macintosh Portable plugged in to the power adapter whenever possible.

When neither of these methods is possible, observe these precautions for recharging and storing the battery:

- Do not leave the battery in the Macintosh Portable for longer than TWO WEEKS without plugging in the power adapter.

- If you store the battery, recharge it overnight before storing it, then store it in a cool, dry place.

- Do not leave a battery in storage for longer than SIX MONTHS without recharging it.

Failure to follow these steps for recharging and storing the battery will result in a dead battery that CANNOT be recharged and will need to be replaced.

Desk Accessories: Troubleshooting Inappropriate Fonts (9/94)

When opening the Chooser to select a LaserWriter, the LaserWriter appears, but with its name displayed in the Cairo typeface.

This article has been archived and is no longer updated by Apple.
If everything else on your system seems to be working, something is probably wrong with your Chooser desk accessory. (This can also happen to desk accessories like the System 6.0.x Find File, and so on.) The information about the LaserWriter coming in over the network doesn't have font information. If your other modeless dialog boxes are working, then the problem must be with the information compiled and generated by the Chooser.

There are several repair options here, depending on exactly where the problem is:

* Reinstall Chooser (with Font/DA Mover if your System is earlier than System 7).

* Reload all System fonts from original disks.

* Reinstall the System file with Installer.

* Zapping the PRAM (under System 6.0.x or 7.x) doesn't usually work.

* Reinstalling the system software (6.0.x or 7.x) doesn't always work.

* Run the shareware control panel ApFont to reset your system file default font (normally Geneva 12) This usually fixes the problem.

* Delete the entire System folder, then reinstall with Installer.

The last option is the most drastic, but also has the greatest probability of fixing the problem the first time.

You can obtain ApFont from AppleLink.

Apple Peripherals & Drivers: Advantage over Third-Party Products

What's the advantage of using an Apple printer instead of one from another manufacturer?

This article has been archived and is no longer updated by Apple.
The Macintosh operating system uses drivers for connecting peripheral devices such as printers. At this time, Apple provides drivers only for its own peripherals, not for third-party products.

Some third-party developers have opted to create drivers for non-apple printers. In most cases these drivers work well. Not all printers or drivers have the same capabilities that our drivers and printers have, while others may have more.

Most software developers develop their software to be compatible with our drivers, but not necessarily with third-party drivers. By sticking with Apple products, you are assured a greater compatibility with off-the-shelf software.

Apple II: Translating Graphics Files to Macintosh

Is it possible to convert ProDOS clip art files to Macintosh SuperPaint files using Apple File Exchange (AFE)? If so, what translator is needed?

This article has been archived and is no longer updated by Apple.

We don't know of a product that converts graphic files between Apple II and Macintosh formats. This type of conversion is one of the most difficult, as the files are usually stored as an approximation of the hardware's display capabilities, which vary greatly between different computer lines.

Though we couldn't find a product that will do this, what you're probably looking for is a utility that will convert a file into a "standard format," such as Graphic Interchange Format (GIF). Once in this format, you could move it to the Macintosh and re-translate it.

CloseView: Conflict Display Cards 48, 824, 824 GC & System 6

I'm having intermittent crashes that seem to be related to the CloseView control panel. I am running System 6.0.x. I frequently need to use CloseView, and my Macintosh crashes almost always when using CloseView.

This article has been archived and is no longer updated by Apple.
There is a known anomaly with CloseView versions prior to 7.0 (that is, those versions before System 7) and the Macintosh Display Cards 4*8, 8*24, and 8*24 GC in the NuBus Macintosh. Your symptoms are typical of this anomaly. The only workaround for using CloseView with these cards is to upgrade to System 7.

CloseView behaves gracefully under System 6 in other Apple-supplied video environments: Macintosh Classic, Macintosh IIsi built-in video, Macintosh IIci built-in video, Macintosh LC built-in video, Macintosh Plus, Macintosh SE, Macintosh SE/30, Two-Page Display Card, Portrait Display Card, and Macintosh II Video Card. We have no data regarding third-party video cards.

The version of CloseView that ships with System 7 is compatible with the 8*24 style of video cards. Users wishing this functionality are encouraged to upgrade to System 7.

Note that though in very brief testing we didn't encounter any problems using CloseView version 7.0 on Macintoshes running System 6.0.x having an 8*24 video card, Apple did not formally test this configuration nor is this a recommended configuration.

An alternative is to use third party CloseView-like programs, such as Stepping Out from Berkeley Systems, Inc. For more information, search under Berkeley Systems.

Apple III COBOL: Using CALL and CANCEL with subprograms

This article has been archived and is no longer updated by Apple.
When a linkage section is used between a calling and a called program and there is I/O (disk read/write, etc.) in the called program, the file I/O instructions are not successfully executed by the called program. Also, the "Cancel" verb does not seem to always free up the entire amount of memory allocated to subprograms.

Page 85 of the COBOL Manual states," If you are not careful in Call/Cancel sequences, you can fragment memory, leaving no room for a new Call, even though the total amount of free memory might be enough." Page 86 says," There is one more complication to consider: any program can be segmented. When you Call a segemented program, The Run-Time System allocates for it enough memory to hold the root segment and the largest overlay." What this all means is that all memory is returned with Cancel but fragmentation could be the problem. A Called module requires contigous memory to be loaded.

Daystar PowerCard: Prevents Start-Up from High-Density Floppy

Can a Daystar 50MHz PowerCard affect SCSI transfers? Does the PowerCard's processor speed adversely affect the SWIM chip upgrade?
This article has been archived and is no longer updated by Apple.
The Daystar 50MHz PowerCard should not affect SCSI transfers.

The SWIM chip that controls floppy drives should not be affected except for one minor problem: you can't start up from a high-density floppy because the accelerator card requires an INIT in order to use high-density disks. High density disks can't be used as startup disks because the INIT must be loaded first.

AFE 1.4: 824 GC Acceleration Problem

Apple File Exchange will not make a clean transfer of data to IBM format when the Macintosh Display Card 8*24 GC's acceleration is on. AFE works okay when the accelerator is turned off.

This article has been archived and is no longer updated by Apple.
This is a known issue with version 1.4 of AFE. The problem occurs with AFE when the Macintosh Display Card 8*24 GC graphic acceleration is turned on and may cause the system to hang, especially when formatting or erasing disks.

The problem does not exist with version 7.0 of AFE. However, AFE 7.0 has only been tested with System 7 and the 7.0.1 version of the 8*24 GC software. The current solution for System 6 users is to turn off graphics acceleration when using disks with AFE 1.4.

Macintosh IIsi: How to Install EtherTalk

How do I install the drivers for an Apple Ethernet board on a Macintosh IIsi?

This article has been archived and is no longer updated by Apple.
This procedure will install the EtherTalk drivers as well as the Network CDEV into your System Folder:

1) The Macintosh IIsi comes with a disk called Network Products Installer. Start your Macintosh IIsi with this disk.

2) Launch the Installer.

3) Click OK.

4) Select EtherTalk.

5) Select the drive you wish to install to.

6) Click on Install (at some point during this procedure, the application will ask you for your EtherTalk Installation Disk).

7) Quit after installation is complete.

8) In the Control Panel, select EtherTalk.

Published Date: Feb 18, 2012

AppleFax Modem: Explanation of Transfer Speeds

The AppleFax Modem's specifications state that it can send at 9600bps, and slower speeds -- presumably to other similar modems' speed.

Is there any detailed information about this modem and the speed at which it transmits files under different conditions?

This article has been archived and is no longer updated by Apple.
The specification you're requesting don't really exist as true benchmarks, as there are too many variables inherent in any data transmission. Most communication hardware specifications cite baud rates and bps ratings, and use that as the basis of comparison with other products.

The AppleFax Modem is an often misunderstood product. It is a Group 3-compatible facsimile device, and communicates with other AppleFax Modems at 9600bps in a modem-like fashion. It's important to note the latter point, as many users mistakenly believe that it also functions as a standard modem.

As far as fax transmission goes, the Group 3 protocols call for extensive error checking, which slows data throughput. In addition, Group 3 fax machines automatically lower their transmission rates based on the noisiness of the phone line. These two factors often make the fax modem appear to be transmitting slower than it actually is.

Macintosh: Basic Troubleshooting for Font Problems

I'm suddenly having problems with the font in one of my Macintosh applications. The font is breaking up and looks like there is no printer font installed. I've reloaded the program, resources, fonts, everything -- but no change.

This article has been archived and is no longer updated by Apple.
In general, font problems can be traced to either corrupt system resources or to a corrupt application. Here is a short troubleshooting procedure you can try to determine which of the two it may be:

Start up the computer with a known good System Tools or Disk Tools startup diskette (one which contains a complete System Folder). This effectively eliminates any conflicts you may be having with system extensions or control panels in your main System Folder. If this solves your problem, then go back to your main System Folder and move all items that did not come with the original system software to another temporary folder, moving one item back in at a time until you diagnose which caused the conflict.

One other possible problem is duplicate System Folders. Your Macintosh may be "switching" to another System on your hard disk and you aren't aware of it. You think you're modifying and testing one System Folder, but your Macintosh is actually using the other System.

Use the Find File desk accessory (or System 7's Find command) to search for multiple System Folders. If you find more than one, trash all but the active System Folder. If that remaining System Folder is still a problem, then move any items from it you want saved to a holding folder and drag the remainder of the System Folder to the trash. Then start up from an Installer disk and reinstall the system.

Macintosh IIfx: Two Internal Hard Drives Not Supported

I have a Macintosh IIfx with two internal 3.5 SCSI drives. The drives are daisy-chained, with the last drive having a terminator and the first one without. I also have an external SyQuest drive with internal termination and a short cable.

I'm concerned that somehow this setup will not work with the Macintosh IIfx and its different bus impedance.

It looks to me like:

1) I need to remove internal termination of SyQuest and use a Terminator II.

2) I need to keep the internal drives the same but add a noise filter, probably at end of internal daisy chain on drive which has termination.

Am I right?

This article has been archived and is no longer updated by Apple.
Your configuration is not an Apple-supported solution. We advise removing the second internal hard drive, particularly with the Macintosh IIfx and its exact termination requirements.

You have the right idea about what it takes to make this work. The termination needs to be augmented with a SCSI Filter on the last internal hard drive and a Terminator II installed on the last external device (and no internal termination).

Macintosh Hard Disk 20: How To Verify HFS Formatting

How do I get a Macintosh Hard Disk 20 to format as an HFS volume?

This article has been archived and is no longer updated by Apple.
Select the Macintosh Hard Disk 20 volume and choose Erase Disk in the Special menu.

You can to see if formatting was successful if there are the two thin lines near the top of the disk window. If you see a one-pixel dot at the left side of those two lines, it is an HFS volume.

Macintosh XL: No Support for LaserWriter LS

I want to use a Macintosh XL with a LaserWriter LS. Can System 6.0.7 run on a Macintosh XL?

This article has been archived and is no longer updated by Apple.
All further Apple development on the Macintosh XL was stopped when it was discontinued. At this time, there are no plans for upgrading MacWorks to System 6.0.7 for LaserWriter LS support.

Published Date: Feb 18, 2012

TA47147_Macintosh_XL_Memory_Upgrades_(TIL08760).pdf

Macintosh XL: Memory Upgrades

Are there any Apple memory upgrades available for the Macintosh XL?

This article has been archived and is no longer updated by Apple.
When the Macintosh XL was available, Apple used 512K memory boards, of which two were supported in the system. AST used to manufacture 1MB memory boards, but they have since discontinued that product.

Sun Remarketing is an excellent source for support on the Macintosh XL. They also carry outdated third-party products for many discontinued Apple products. They may have some of those AST board in stock.

On AppleLink, you can find contact information on a company mentioned in this article by clicking the "Library Index" button in the lower-center of the Tech Info Library search window, then opening the "Third Party Company Directory" folder.

LaserWriter: Improving the Speed of a Shared LaserWriter

I have a 15-node TOPS network with a shared LaserWriter IINT. I'm not happy with the printing speed across the network and I'm considering upgrading to a LaserWriter IINTX. Most of the documents we print are 1 to 4 pages with only 3 to 4 fonts. Is the bottleneck the LocalTalk speed, or could a LaserWriter IINTX significantly improve printing speed? Can you tell me how a LaserWriter IINTX could increase speed, and how much improvement to expect?

This article has been archived and is no longer updated by Apple.
Upgrading to a LaserWriter IINTX will definitely help performance some, but it's important to consider other factors that may also help. The principal items that affect printing to a PostScript LaserWriter with a given application (not necessarily in this order) are:

- The LaserWriter's CPU performance.

- The type of print job: complex graphics or text.

- Whether the required fonts are resident in the printer or need to be downloaded.

- The type of connection to the host: serial or LocalTalk.

- The host's performance: how fast it can prepare and send data.

The environment may also play a major role in printing performance. Connection to a LocalTalk network adversely affects the performance of many LaserWriters if that network is used for file services such as an AppleShare File Server or TOPS installation. The LocalTalk bandwidth can be used up, resulting in poor network and printing performance.

From what you've told us about your installation, it doesn't sound like upgrading to a LaserWriter IINTX will help much. You may see a mild improvement in print speeds, but unless you print complex graphics as well as text, you won't see a dramatic change.

The type of Macintosh, the system software versions, and the applications you use can affect speed quite a bit.

Printing slows down if you repeatedly use fonts (TrueType or PostScript) that must be downloaded. If this is the case, we recommend that you make a habit of downloading the most frequently used fonts to the LaserWriter with the LaserWriter Font Utility. Downloading fonts once between power cycles instead of for each print job improves speed on both the LaserWriter IINT and IINTX.

The LaserWriter IINTX does have the advantage of optional memory upgrades for additional fonts and performance. A hard disk is also available for the LaserWriter IINTX to download fonts only once.

Apple HD Setup: Why 80MB Drive Formats to Only 76.8MB

I've noticed that the new Apple 80MB internal drives only format to 76,800 Kbytes usable! Is there any reason for this? (The old drives formatted to the entire 80MB.)

This article has been archived and is no longer updated by Apple.
Earlier versions of HD Setup initialized a volume to its maximum formatted capacity. Drives of similar advertised capacity have slightly varying total formatted size.

The release of the Apple Tape Backup unit lets you do a mirror-image backup of your drive. But in order to restore a mirror image backup, the volume that is being restored to must be of like or greater capacity than the volume from which the data came.

If, for instance, you had a failing hard disk that could be formatted to 78MB, did a mirror-image backup, had the drive replaced with one that could be formatted to only 76MB, you wouldn't be able to restore your work.

Apple modified HD Setup so that it formats each series of drive we sell to a like-total formatted size for that series, regardless of vendor. In the case of the nominally 80MB drive, 76MB is the lowest common denominator of all vendors that we use.

You may be able to reclaim some of the unused 4MB by using a third-party initialization application, but this is not guaranteed nor supported by Apple.

ImageWriter: First printed line is expanded or crunched

This article has been archived and is no longer updated by Apple.
When you print a file on the Imagewriter, sometimes the first printed line at the beginning of the paper is crunched or expanded. This problem sometimes occurs after you take the paper out of the platen: you may have left the tractor gears in a position "between linefeeds". Solve this problem by doing a form feed right every time you reload the printer with paper.

Sometimes the paper is not held tight enough by the rollers, especially when you use cut sheets. Solve the problem by "burping" the printer: turn the printer off and on so the printhead moves back and forth and the gears are tightened.

Macintosh: Troubleshooting Invisible Folders Problem

When opening a Macintosh-formatted floppy disk from within Microsoft Works to select a file, no folders appear. But the folders appear normally in the Finder directory. The files are all available, but the folders on the disk are invisible. How can we get the disk back to normal?

This article has been archived and is no longer updated by Apple.

1) It's possible that the disk directory got corrupted, causing the problem you are seeing. Rebuild your Desktop by holding down the Command and Option keys while inserting the diskette. Run Disk First Aid to repair any directory damage.

2) Someone may have made the folders invisible. Use a utility such as ResEdit or Symantec Utilities to check this.

3) If running System 7.0 or 7.0.1, make sure to obtain System 7 Tune-Up version 1.1.1 or greater. Running Tune-Up 1.1.1 or greater will prevent a problem from occurring where folders and files begin to disappear from the desktop, but are in fact still intact and available.

System 7: Can‘t Run from Single 800K Floppy Disk

Article Change History

08/18/92 - CORRECTED
* To clarify that a high density (1.4MB) startup floppy is possible.

Is there a way to create a bootable floppy of System 7?

If not, what is Apple's recommendation for doing diagnostics in the event of a system hang on startup or a hard disk crash?

This article has been archived and is no longer updated by Apple.
It is not possible to create an 800K system startup floppy disk, though a high density (1.4MB) floppy will hold a minimal System 7. For those Macintoshes that have an Apple (FDHD) SuperDrive, making a bootable floppy is simply a matter of running the System 7 Installer program, choosing customize, and selecting "Min System" for your Macintosh model.

The initial recommendation for troubleshooting System 7 is to hold down the Shift key on startup to temporarily disable any system extensions (INITs). Some other suggestions for system software troubleshooting:

1. Attach an external hard drive that has System 7 on it and set startup. Make sure this hard drive has appropriate and latest virus checkers installed.

2. Run standard hardware diagnostics to check the hardware.

3. Completely replace the System 7 software if removing the system extensions doesn't help. This is where it might be useful to have a 1.4MB startup floppy, so that you can at least get to the hard disk to remove the damaged system files and set aside other files you want to save.

Macintosh: Explanation of "About This Macintosh..."

When I choose "About This Macintosh..." from the Apple menu, I get information about my computer's memory and how it's being allocated. When I look at how much memory my applications are using, I typically see a grayed bar that's fully or partially filled by a black bar. Sometimes the black bar moves around.

What do the black and grey bars indicate? I have always thought the gray was for how much memory the program had reserved for itself and that the black was how much memory it was currently using.
This article has been archived and is no longer updated by Apple.
The total bar (black + gray) equals the amount of RAM allocated to the application, with the black portion indicating the amount of RAM currently used by that application. Technically, the program would have to use the operating system's memory manager for the black portion to be completely accurate, and some programs don't do that. The black portion fluctuates in proportion to actual RAM in use.

Notes:

* Under System 6.0.x, you get the same information with the "About The Finder..." item under the Apple menu.

* Under System 7.x, you can get an "About The Finder..." choice under the Apple menu instead of "About This Macintosh..." by holding down the Option key. When you select this menu item, you'll see the mountain Finder graphic.

* Performa systems display the same information with the "About This Computer..." item under the Apple menu.

Using Lisa 2.0 Files With Lisa 7/7

This article has been archived and is no longer updated by Apple.

When you open a document with a Lisa application, there must be enough disk space to retain the original document while you work - in the event you later choose "revert to previous version." Even more disk space is required to enable you to use "undo." This is why you may see the message "Not enough room to open file" when you try to read a Lisa 2.0 document stored on diskette by Lisa 7/7. If this happens, move the document to the hard disk, where you are likely to have more free storage space. You should then be able to work on your document with no problems.

Macintosh: Do Not Split ADB Signal

Some Macintosh computers, like the Macintosh IIsi, have only one ADB port in the back. Can I make up my own ADB "T" plug or "Y" cable, so that two ADB sockets would be provided from the one port? Will the two ADB devices interfere with each other?

Another way to phrase the question: on a Macintosh with two ADB ports on the back, does each port come off a different and separate part of an interface chip, or are the two connections "common", so that pin 1 on connector 1 is connected to pin 1 on connector 2?

This article has been archived and is no longer updated by Apple.
We do not recommend splitting the ADB signal, because it could cause difficulties with signal integrity. The signal is not very strong, and if split would be even weaker.

On a Macintosh with two ADB ports, both ports both go to the same ADB controller chip, but are physically separated to deliver the full signal down the bus.

Macintosh: How To Make "Curly" Quotation Marks

My Macintosh (using New York font) makes quotation marks angled only one way. How can I produce the opposing quotation mark?
This article has been archived and is no longer updated by Apple.
Here's how to produce "curly" quotes from the Macintosh keyboard:

For this character	Press these keys
"	Option-[
'	Option-]
"	Option-Shift-[
'	Option-Shift-]

Some word-processing applications (MacWrite is one) can be set to automatically produce the appropriate "curly" quotes when you type ' or ".

Here's how to use the Key Caps desk accessory to see what characters are available to you:

1) Once you select Key Caps from the Apple menu, you see a display of all characters available in the current font -- actually, all those you can produce without using the Shift, Command, or Option key.

2) To see what characters you can make with various combinations of the Shift, Control, and Option keys, just press those keys on the keyboard.

3) To change to another font, select it from the Key Caps menu.

Apple IIe Card: Using with Apple High Resolution 13-inch Monitor

Are there any display problems associated with connecting the Apple 13-inch High Resolution Monitor to a Macintosh LC with an Apple IIe Card? Will some objects display with incorrect aspect ratios?

This article has been archived and is no longer updated by Apple.
There shouldn't be any problem using the Apple High Resolution 13-inch Monitor with the Apple IIe Card. Using a 13-inch RGB monitor on the Macintosh LC with Apple IIe emulation should not affect the aspect ratio of any object. Circles should still be circles. However, when running Apple IIe emulation, you can only use certain Apple IIe text display modes:

- 80 columns, 24 lines, 5x7 dot matrix

- 40 columns, 24 lines, 5x7 dot matrix

- All text appears on the screen as normal, inverse, or MouseText characters

Apple PC 5.25 Drive: Troubleshooting Slow Disk Recognition

My Apple PC 5.25-inch floppy takes about a minute for an inserted 5.25-inch disk to be recognized by my Macintosh. Is this normal?

This article has been archived and is no longer updated by Apple.
It depends on the amount of information on the MS-DOS diskette, but there are probably some other factors involved to bring the access time to a full minute. More than likely there are other INITs, CDEVs or applications (if you're running under MultiFinder) that are stealing CPU time away from Apple File Exchange. You can easily check this by starting up with a floppy under Finder-only and launching AFE.

Another possibility is that AFE is running out of memory. If you're running MultiFinder, try boosting the RAM allocation by 200K or so.

Networks: Selectively Securing Zones and Devices

Is there any product available that will allow a network administrator to hide zones or services on a selective basis? I have two divisions on a single network that want to keep their printers separate. Each zone contains printers from only one division.

This article has been archived and is no longer updated by Apple.
There are several products available to isolate a LaserWriter. Some are hardware, some are software, but most work on the level of zones, hiding devices within a zone to the entire Internet.

There are several options available to allow zone and device hiding, some are LocalTalk-to-Ethernet routers, and some are Ethernet-to-Ethernet routers. To locate a vendor's address and phone number, use the vendor name as a search string.

Apple Internet Router
Apple Internet Router supports three "families" of access methods: AppleTalk, half-routing, and tunneling. Each family may include more than one specific access method. For example, LocalTalk, EtherTalk, and TokenTalk are all AppleTalk access methods.

One of the more interesting features of Apple Internet Router is device hiding, which lets you select any device or devices on your local network to be hidden from users on other networks. Device hiding is configured in the "Hide Devices..." dialog, which is accessed by clicking the "Hide..." button in the Port Info window.

You can elect to hide no devices, all devices, only a specific list of devices, or all devices except a specific list. You can hide your selection from all other ports or from a specific other port.

The administrator must use good judgment when setting up the list of hidden devices (or the list of not hidden devices). If the list contains more than a few devices, it will adversely affect performance.

In order for device hiding to be effective in a loop environment, all routers on a given network must hide the same devices. Otherwise, a "hidden" device would be accessible through another router that isn't hiding it.

Device hiding is not foolproof. Users could obtain a hidden device's AppleTalk address through some means other than looking for it on their network, such as running Inter*Poll on a portion of the internet that does have access to the device. Armed with that information, a user could access the device programmatically, even though the device is theoretically hidden.

AppleTalk Router Security Features: LocalTalk-to-Ethernet Routers

Cayman Systems GatorBox
Zone filtering prevents users in the filtered zone from seeing other zones on the network. This also prevents users in zones outside of the filtered zone from seeing devices in the filtered zone.

Laser filtering is, in a sense, a subset of zone filtering. Where the zone filtering shields all of the devices from the outside, laser filtering allows you to hide only LaserWriter printers from anyone outside of its AppleTalk zone. This also prevents users in the filtered zone from seeing LaserWriter printers in other zones.

Tilde filtering allows you to hide any device with a tilde character (~) at the end of its name from being seen by anyone outside of its zone.

Shiva FastPath
The Stay in Zone option prevents users in the filtered zone from seeing other zones on the network. This also prevents users in zones outside the filtered zone from seeing devices in the filtered zone.

LaserWriter Security is, in a sense, a subset of zone filtering. Where the zone filtering shields all of the devices from the outside, laser filtering allows you to hide only LaserWriter printers from anyone outside of its AppleTalk zone. This also prevents users in the filtered zone from seeing LaserWriter printers in other zones.

Tilde Security allows you to hide any device with a tilde character (~) at the end of its name from being seen by anyone outside of its zone.

NRC 2000
The Insecure option allows you to define sections of your Internet as insecure. Insecure network's routing information is not propagated to any other section of the network, thus providing a way to control who can and cannot access the secure sections of the Internet.

APT
APT Communications announced an update to their AppleTalk routers. They now support device security across zones. Users can, for example, hide their LaserWriter from anyone not in their zone. You can hide other devices, such as file servers and NetModems.

You can allow other users on different zones, different sets of access to different devices. For example, Zone A may have no access to your

LaserWriter, but still have access to a File Server, while Zone B has access to all LaserWriter printers, but not AppleTalk ImageWriter printers or NetModems.

APT routers connect multiple LocalTalk, Ethernet, WAN, and Serial networks and support Phase II AppleTalk.

AppleTalk Router Security Features: Ethernet-to-Ethernet Routers

NRC Multigate Macintosh
The Insecure option allows you to define sections of your Internet as insecure. The Insecure network's routing information is not propagated to any other section of the network, thus providing a way to control who can and cannot access the secure sections of the Internet.

Cisco (CGS/MGS/AGS)
The Cisco router offers the ability to set up access lists that allow controlled access to your network. Access lists are set up to filter all inbound network traffic from any network listed in the access list. It excludes traffic from networks listed in the access lists from your network. Traffic from your network is still propagated to all other segments of your Internet.

International Transware (InterTalk)
This is a 2-port LocalTalk router that lets the user create blind and private zones. Users in a blind zone cannot see or use the resources of the AppleTalk Internet, but users outside of the blind zone can see and access any of the services in the blind zone. Private zone users have access to the entire Internet, but users outside the private zone cannot see or access any of the services of the private zone.

NetCounter
NetCounter limits use of a LaserWriter by using the user name as specified in the Chooser for all accounting and access control. Therefore, NetCounter does NOT provide a secure environment against knowledgeable users who are motivated to circumvent the NetCounter controls. The security can be increased to some degree by removing the Chooser Desk Accessory, if the Chooser is not required.

NetCounter is an application that downloads PostScript code to PostScript printers. Thus, NetCounter does NOT support QuickDraw printers such as the LaserWriter IISC. Because the accounting code executes on the printer rather than on the Macintosh, you install the NetCounter application only on the administrator's Macintosh, not on each Macintosh on the network.

The NetCounter code and log data normally reside in the printer memory. Therefore, in the event of a power failure or printer reset, the log data in the printer memory is lost. A Macintosh running NetCounter can request transfer of log data from the printer to the Macintosh, so the administrator can limit the amount of information lost in the event of a power failure. If the printer has a hard disk attached (like a LaserWriter IINTX with hard disk), the log data is automatically saved to the hard disk, so that no information is lost in the event of a power failure. If the printer has the new PostScript ROMs installed (such as M0445LL/A LaserWriter IINTX Upgrade Kit or M6215/A Printer), you can install the NetCounter PostScript code on the printer's hard disk. This allows NetCounter to start up automatically after a power failure or whenever the printer is turned on, and the code does not need to be manually downloaded. This is the recommended configuration.

Within the constraints described, NetCounter offers the following features:

* Provides a count of the number of pages printed by each user.

* Provides two different approaches to control access to the printer:
- Grant access to specific users (deny all other users).
- Deny access to specific users (grant access to all other users).

* Provides miscellaneous control and display of printer parameters
For example, enable/disable printer startup page, or set the manual feed timeout.

* Prevents the PostScript Trojan horse (which changes the printer's password) from infecting the printer while NetCounter is running.

NetCounter can control multiple printers, but it is awkward, with the current version, to specify a different access control list for each printer.

Note: This article provides information about a non-Apple product. Apple Computer, Inc. is not responsible for its content. Please contact the vendor for additional information.

TA47179_System_DesignCAD_DD_Compatibility_(TIL08798).pdf

System 7: DesignCAD 2D/3D Compatibility

Is DesignCAD 2D/3D, from DesignCAD, Inc., compatible with system software version 7.0?

This article has been archived and is no longer updated by Apple.
DesignCAD 2D/3D works with system software version 7.0 except on the Macintosh Plus, Macintosh SE, and Macintosh Portable. On these Macintosh models, DesignCAD 2D/3D fails to recognize the presence of 32-bit QuickDraw, which is built into version 7.0, and gives the user a message to install 32-bit QuickDraw.

At this time, there is no known workaround.

On AppleLink, you can find contact information on a company mentioned in this article by clicking the "Library Index" button in the lower-center of the Tech Info Library search window, then opening the "Third Party Company Directory" folder.

Apple Modem: Using one from within an Applesoft BASIC program

This article has been archived and is no longer updated by Apple.
If you wish to use an Apple Modem from within an Applesoft BASIC program, you must write your own software to do so; you must be prepared to read each character you send, though, since the Apple Modem echoes each character sent through it.

Following is an example routine for dialing a number. NOTE: this routine is only meant to illustrate how to read each character after sending it. The routine does dial a number, but this routine cannot stand alone: notice how it ends without completely flushing the input from the modem.

```
10 D$ = CHR$(4)
20 S$ = "AT D123-4567"
30 PRINT D$;"PR#2"
40 PRINT D$;"IN#2"
50 FOR I = 1 TO LEN(S$)
60 PRINT MID$(S$,I,1);
70 GET X$
80 NEXT I
90 PRINT
100 PRINT D$;"PR#0"
110 PRINT D$;"IN#0"
```

WARNING: When trying to access the modem from the program, if you use PRINT CHR$(4);"PR#2" and/or PRINT CHR$(4);"IN#2", followed by CTRL-A T, the computer hangs and BASIC program control is lost. That's because once you send a CTRL-A T, the firmware takes over and is in control until you type CTRL-A Q.

To send AT commands to the modem, send only the "PR#2"; then, using a PRINT statement, you may send whatever you wish. For example:

```
10 D$ = CHR$ (4)
20 PRINT D$; "PR#2"
30 PRINT "ATDT1231234"
40 END
```

will dial 123-1234. You could also replace line 40 with

```
40 PRINT D$; "IN#2" and add,
50 PRINT CHR$ (1); "T"
```

and you'd be in terminal mode.

System 7: Invisible Icon File Sizes Not Included in Folder Size

Article Change History

09/11/92 - REVIEWED
* For technical accuracy.

I received an out-of-space error message when I tried to copy some folders to another disk even though the available disk space was more than enough to hold the folders I was moving.

This article has been archived and is no longer updated by Apple.
When you copy folders with custom icons to another disk, the sizes of the invisible icon files are not included in the total folder size. This can result in the out-of-space error message you received.

Published Date: Feb 18, 2012

Network Assistant: Observation Eyes Appear Even When Checkbox Is Deselected

Network Assistant observation eyes may appear in a client's menu bar even if that option is deselected.
This article has been archived and is no longer updated by Apple.

Symptom

The "Show me when I am being observed" checkbox is deselected in the Network Assistant Security application on the client computer. However the eyes still appear in the client's menu bar when the client is being observed from the Network Administrator station. This situation can occasionally occur when there is an issue with the Network Assistant preferences file.

Solution

1. Drag the file "Network Assistant Prefs" from the Preferences folder on the client to the Trash.
2. Restart the client computer.
3. Set up the client preferences with the Network Assistant Security application.

PrintMonitor Alerts: Conflict with LW Manual Feed (11/94)

I use manual feed to print to my Personal LaserWriter SC with background printing turned on. After the print job is finished, I get a dialog box stating, "Please bring PrintMonitor to the front. The Personal LaserWriter SC is waiting for a sheet of paper." If I insert a sheet of paper, I get a second printout of the last page printed, whether it's a 1-page or multi-page document.

Sometimes it asks for another sheet of paper over and over in an endless loop; other times, it asks only once or twice. Occasionally, if I load an extra sheet of paper before printing, I don't get this message and the page prints fine.

This article has been archived and is no longer updated by Apple.
This is related to the PrintMonitor default Preferences settings. To correct the problem, use this procedure:

1) Launch the PrintMonitor application.

2) Choose Preferences from the File menu.

A Preferences window appears with three section:

* Show the PrintMonitor window when printing:

o Yes
o No

The default is No.

* When a printing error needs to be reported:

o Only display diamond in Application menu
o Also display icon in menu bar
o Also display alert

The default is to show all displays.

* When a manual feed job starts:

o Give no notification
o Display icon in menu bar
o Also display alert

The default is to give notification and display both icon and alert.

3) In the "When a manual feed job starts:" section, click the "Give no notification" button.

If you still have the problem after you've made this adjustment, change the settings in the "When a printing error needs to be reported:" section to "Only display diamond in Application menu" by clicking that button.

This problem seems to be caused by a conflict between alert messages and manual feed and may happen with other LaserWriter printers.

Sherlock 2: How to Save Changes to Volumes and Search Engines

This article explains how to save changes to the volumes and/or search engines used by Sherlock 2.
This article has been archived and is no longer updated by Apple.
In order to save the volumes or Internet search engines selected to perform searches:

1. Select the volumes you would like to search by placing a checkmark in the volumes box (see Figure 1).
2. When you have the volumes you would like to keep as a default set, change the channel. For instance, if you are in the file search, change the channel to an Internet search.

Figure 1 Sherlock 2 window

The next time you open Sherlock it retains these selections.

Network Assistant 4.0.x: Errors When Remotely Shutting Down or Restarting

Error messages may appear when trying to remotely shut down or restart a client workstation running Macintosh Manager and Network Assistant 4.0

This article has been archived and is no longer updated by Apple.

Symptom

One of the following messages appears when trying to shut down a client workstation from the administrator's console:

- There is a modal dialog on the client.
- You are not permitted to change file sharing settings.

Products affected

- Macintosh Manager
- Network Assistant 4.0

Solution

When using Network Assistant's Shut Down or Restart command you have the option to let users save their work before the workstation restarts, or to restart immediately. If you see an error that a modal dialog is on the screen which prevents the client workstation from restarting, choose Restart Immediately. If you see an error about file sharing, choose Allow user to save their work.

HyperCard 2.0: How to Change Address Book‘s Font Size

Is there any way to increase the font size of the mailing labels that HyperCard prints from the Address Book? The default point size for the labels is very small.

This article has been archived and is no longer updated by Apple.
To do this, you need HyperCard 2.0, which lets a text field contain multiple fonts, styles, and sizes.

1) Select the text you want to change.

2) Either choose "Text Style..." from the Edit menu, or make a choice from the Font or Style menu.

You can also use HyperTalk to find or set the attributes of any range of characters.

NuBus Ethernet Card: 1990 Revision Didn‘t Change Functionality

Apple introduced a new version of the Macintosh II NuBus Ethernet Card in December 1990, replacing the old version. Both boards have the same part number: M0410LL/A.

What is the difference between the two cards?

This article has been archived and is no longer updated by Apple.
Whenever Apple Manufacturing changes a board layout or card design these are considered "revisions". In the case of the December 1990 revision, it was a board layout change. There were no changes to functionality or power requirements.

Apple IIe Card: Which Drives are Supported

1) What disk drives does the Apple IIe Card support?

2) Why hook up a UniDisk 3.5-inch to the Apple IIe Card?

3) How do I eject the internal 3.5-inch disk?

4) If I connect a compatible Apple 5.25 Drive to this Macintosh LC, can I run regular Apple IIe software?

This article has been archived and is no longer updated by Apple.

1) The Apple IIe Card supports the following drives:

* The two Internal Macintosh LC SuperDrive disk drives

* One UniDisk 3.5-inch (part number A2M2053, white).

* Two Apple 5.25-inch Disk Drive (part number A9M0107, platinum) connected to the drive cable or UniDisk 3.5. Note: If you hook up a UniDisk 3.5-inch and Apple 5.25-inch, the UniDisk 3.5-inch goes first.

The Apple IIe Card does NOT support:
* The Apple 3.5-inch
* UniDisk (beige 5.25-inch)
* DuoDisk
* Disk II

The older 5.25-inch drives use -12 volts, which the Macintosh LC does not support.

2) Some copy-protected applications require a UniDisk 3.5-inch as part of the configuration, or they won't work correctly. Nor do they work on the SuperDrive inside the Macintosh LC.

3) To eject a disk from an internal 3.5-inch disk:

* Press Command-Shift-1

* Enter the Option Panel (Command-Control-Esc) and press the Disk Eject button.

4) Yes. In Apple IIe mode, the Macintosh LC will function exactly as an Apple IIe.

Apple II BASIC: How to Convert Into Macintosh QuickBasic

Is there a way to convert Apple IIe/IIGS BASIC files into Microsoft QuickBasic files for the Macintosh?

This article has been archived and is no longer updated by Apple.
Yes, follow these steps:

1) Save a listing of the program as an ASCII text file.

2) Transfer the file to the Macintosh using Apple File Exchange.

3) Import it directly into Microsoft QuickBasic. QuickBasic accepts ASCII Text Files.

4) Now, it's just a matter of modification (if needed). According to Microsoft, some programs work even without conversion.

PowerBook: Power and Battery Frequently Asked Questions, Part II

This article contains frequently asked questions (FAQ) regarding PowerBook batteries and power issues, with answers to those questions.

For Part I of this FAQ, please see article 18241: "**PowerBook: Power and Battery Frequently Asked Questions, Part I**"

This article has been archived and is no longer updated by Apple.
Questions answered in this article:

1. How can I increase the battery life of my PowerBook?
2. What is processor cycling and how do I turn it off?
3. Can I charge my PowerBook from a car cigarette lighter?
4. I am taking my PowerBook to another country, do I need a power converter?
5. Can the PowerBook 5300 or 190 use two batteries simultaneously?
6. Where else can I go for answers about my PowerBook?

Question 1: How can I increase the battery life of my PowerBook?

Answer: The two operations of your portable computer that drain the battery the most are using the backlight on your screen and using your hard drive. To increase battery life reduce these two factors. Set your hard drive to spin down quickly and turn off your backlight or sleep the machine when not in use. In addition, turning on processor cycling or using the slower processor speed available on some models will increase your battery life. These options are available in the PowerBook or Energy Saver control panel.

Some steps to reduce hard drive usage are disconnecting any external peripherals, removing PC (PCMCIA) cards, increasing your disk cache in the Memory control panel, increasing the memory allowance for programs, and running frequently used programs off a ram disk, esp. if they are disk intensive.

For more information on this subject read article 50666: **"Tips for maximizing your PowerBook and iBook battery charge."**

Question 2: What is processor cycling and how do I turn it off?

Answer: All PowerBook models implement a feature called processor cycling intended to save battery life. This feature activates when the computer detects that the keyboard, mouse, track ball or Trackpad has not been used for more than a few seconds. At this time, the processor speed is reduced and all processing functions become extremely slow. Processor cycling will not activate while the computer is doing any sort of data transfer.Processor cycling also reduces the overall average power the CPU dissipates and helps keep the average CPU temperature lower.

It is recommended to keep the processor cycling option enabled unless the user finds specific applications that are affected by this cycling in which the interruptions are intolerable. Note that processor cycling is on by default, and although it is intended to for battery life conservation, it will also activate while running off AC power.

The method of turning off processor cycling will depend on the version of the system software you are using:

System 7.0.1

1. Open the Portable control panel.
2. While holding down the Option key, click on the word "Minutes".
3. Select Don't Rest and click OK.

System 7.1

1. Open the PowerBook control panel.
2. While holding down the Option key on the keyboard, click the Options... button in the control panel.
3. Select "Don't allow cycling".

System 7.5 through Mac OS 8.1 (except PowerBook G3 Series)

1. Open the PowerBook control panel.
2. Make sure the toggle switch in the control panel is set to Easy.
3. While holding down the Option key on the keyboard, drag the toggle switch from Easy to Custom and let go.
4. Uncheck the "Allow processor cycling - more battery savings" checkbox.

Mac OS 8.5 or later (or PowerBook G3 Series running Mac OS 8.1)

1. Open the Energy Saver control panel.
2. Click on the Advanced Settings button.
3. In the "Settings for:" pull-down menu, select whether you will be adjusting the settings for Battery or Power Adapter.
4. In the section, Additonal Power Savings, deselect Allow processor cycling.

Question 3: Can I charge my PowerBook from a car cigarette lighter?

Answer: Yes, there are several commercial auto adapters on the market designed specifically for charging portable computers. Be sure to get one designed for a PowerBook computer. Alternatively you can obtain an inverter which takes the 12v DC power from the cigarette lighter and converts it to the correct AC voltage for the country it was purchased in (110 V in US, 220 to 240 V in Europe and Asia). You can then plug in your standard PowerBook AC adapter to charge the battery.

Question 4: I am taking my PowerBook to another country, do I need a power converter?

Answer: All of the PowerBook AC adapters are capable of AC power specifications from around the world. To verify, there should be a line on the AC adapter stating something to the effect of:

AUTO RANGING INPUT:100-120V~1.5A 200-240V~0.75A.

If your AC adapter has this on it, it will adjust to the proper voltage.

Note: You will need an adapter to allow you to plug your power cord into a foreign plug. These are available at most electronic stores and travel stores.

Question 5: Can the PowerBook 5300 or 190 use two batteries simultaneously?

Answer: Yes, the PowerBook 5300 and 190 expansion bay (where the floppy disk drive normally is) can accept a battery. BTI (800-982-8284) was planning to release such a battery. Since the expansion bay does not pass AC power through, any battery used through the expansion bay will require its own power supply for charging.

Question 6: Where else can I go for answers about my PowerBook?

Answer: If you haven't done so already, check the other PowerBook FAQ documents in the Apple Knowledge Base at **http://kbase.info.apple.com**. This contains thousands of technical articles which are easily searchable using boolean search strings.

Mac OS X Server 1.x: Services FAQ, Part II

This article contains frequently asked questions about Mac OS X Server, with answers to those questions.

For Part I of this article, please see article 60167: "**Mac OS X Server: Services FAQ, Part I**"

See also the following articles:

Article 60165: "**Mac OS X Server: General FAQ**"
Article 60166: "**Mac OS X Server: Operating System FAQ**"
Article 60168: "**Mac OS X Server: NetBoot/Macintosh Manager FAQ**"
Article 60169: "**Mac OS X Server: Hardware and Compatibility FAQ**"
Article 60170: "**Mac OS X Server: Pricing and Availability FAQ**"

This article has been archived and is no longer updated by Apple.
Note: This article pertains to Mac OS X Server versions 1.x, which were released prior to May 2001.

Questions answered in this article:

1. Is QuickTime streaming available with Mac OS X Server?
2. Is print spooling available with Mac OS X Server?
3. How many clients can Mac OS X Server support?
4. Can Mac OS X Server run all these services at the same time?
5. Do all these Mac OS X Server services use the same user and group information?

Question 1: Is QuickTime streaming available with Mac OS X Server?

Answer: A preview version of the QuickTime Streaming Server was included with Mac OS X Server. The final version of this software was released by Apple 19 April 1999 and is available for downloading from the Apple Software Updates Web site at http://www.apple.com/swupdates. QuickTime 4 is required to view movies streamed by QuickTime Streaming Server. QuickTime 4 Pro is required to created streaming movies.

Question 2: Is print spooling available with Mac OS X Server?

Answer: Yes. Macintosh customers can use the Desktop Printer Utility LPR support to connect to a Mac OS X Server print spooler. Mac OS X Server can spool files to any PostScript-capable network printer over either AppleTalk or TCP/IP. There are also a number of third-party print-spooling products available for the publishing industry

Question 3: How many clients can Mac OS X Server support?

Answer: The Macintosh Server G3 with Mac OS X Server configuration running a single service, if properly configured, can support:

- Millions of Web transactions a day
- Approximately 50 NetBoot clients
- Over a thousand AppleShare clients
- Thousands of Macintosh Manager clients

The actual number of clients supported depends on your network environment, usage scenarios, and hardware configuration.

Question 4: Can Mac OS X Server run all these services at the same time?

Answer: Not quite. Thanks to the power of preemptive multitasking, you can efficiently run multiple services on a single server. However, this requires more memory than running a single service, and it reduces the maximum load sustainable by any given service. The exact details depend strongly on your usage patterns. More information on optimal configurations will be available in Apple's Tech Info Library at til.info.apple.com.

Question 5: Do all these Mac OS X Server services use the same user and group information?

Answer: No. Apple file services (and NFS) use the native users and groups based on NetInfo, allowing the information to be shared among computers. Macintosh Manager maintains its own user and group information, as does Apache. WebObjects applications can be designed to work with Apache users and groups, but often verify against the underlying database used by the application.

AppleWorks 5 and Macintosh Manager: XTND Alerts

An alert box may appear if you try to use AppleWorks 5 with XTND translators on a Macintosh Manager client.
This article has been archived and is no longer updated by Apple.

Symptom

When you save or import documents in various file formats an alert box with this message appears:

> "The translator 'x' could not be found. Please delete the file 'XTND Translator List' from your preference folder and relaunch AppleWorks

Solution

1. If you are running Macintosh Manager 1.3, install the Security Bypass extension or update to Macintosh Manager 1.4.1, both of which are available from the Apple Software Updates Web site at http://www.apple.com/swupdates.
2. If you are running Macintosh Manager 1.4 or 1.4.1, open the Privileges pane of the Workgroups pane, and deselect the "Enable file level security on Mac OS 9 workstations" option.

iMovie 2.1 for Mac OS X: Playback Clip in Full Screen Starts at Beginning of the Clip

In iMovie 2.1 for Mac OS X, playing a clip in Full Screen mode plays from the beginning of the clip, instead of from the position of the playhead on the selected clip.

This article has been archived and is no longer updated by Apple.

Symptom

In previous versions of iMovie, Full Screen playback of a selected clip would play starting from the position of the playhead. In iMovie 2.1 for Mac OS X, playback starts from the beginning of the clip. If no clip is selected, Full Screen playback starts from the beginning of the project.

Solution

Apple is aware of this behavior, which only affects full screen playback. You can preview your clip or project using the Viewer to start from the position of the playhead.

TA47197_Apple_IIe_Emulation_via_In_A_Mac_(TIL08812).pdf

Apple IIe Emulation via][In A Mac

Does the Apple IIe Card work in the Macintosh IIsi? Is the Macintosh LC the only computer available that runs Apple IIe software?

This article has been archived and is no longer updated by Apple.
The Apple IIe Card is designed exclusively for the Macintosh LC.

There is an alternative for Apple IIe emulation in other Macintosh models. The product is called "][In A Mac". Contact the vendor for compatibility information.

More information is available in the Redgate Product Registry on AppleLink.

Published Date: Feb 18, 2012

Macintosh Display Card 824 GC: Troubleshooting Screen Flicker

My Macintosh IIfx with a Macintosh Display Card 8*24 GC is having intermittent screen flicker. I've swapped out the Macintosh Display Card 8*24 GC, the DRAM in the Display Card, the monitor, and the logic board.

This article has been archived and is no longer updated by Apple.
The flicker may be caused by the Macintosh Display Card 8*24 GC CDEV. Turn off the CDEV and restart the computer. If the flickering goes away, then the problem is related to software corruption or hardware/software incompatibility. This incompatibility can range to other hardware cards installed, especially other video cards made by third-party vendors, to incompatible software packages or other third-party INITs.

With the Macintosh Display Card 8*24 GC CDEV turned off, the card acts just like a Macintosh Display Card 8*24. If the flickering still occurs, you may be encountering an environment issue related to EMF (electromagnetic interference).

Published Date: Feb 18, 2012

Macintosh: Troubleshooting Random Sound Problems

I'm getting a random monkey alert sound on my Macintosh even though the alarm is off and the regular beep sound is selected in the Control Panel. I have no special sound INITs or CDEVs.

This article has been archived and is no longer updated by Apple.
The sounds selected for the beep are loaded into RAM during startup. It's possible that your System Folder may be corrupted and is pointing to another beep sound.

Try starting up from a locked System disk and let it sit for a while to see if it does random beeps. If this doesn't fix things, trash and reinstall the System Folder. If the problem still persists when you start from the floppy, then you may have a hardware failure.

You also mentioned no special CDEVs and INITs being used. Were you referring to sound-type INITs? Other INITs that have some time/delay activation might also cause similar symptoms: SuperClock, screen savers, and spelling checker CDEVs to name a few.

WebObjects 4.5.1: Adaptor Source Will Not Compile on Mac OS X Server 1.2

This article describes how to fix the WebObjects 4.5.1 adaptor source so it will compile on Mac OS X Server 1.2
This article has been archived and is no longer updated by Apple.

Symptom

After running the make command or building in ProjectBuilderWO you see these messages:

```
In file included from ../Adaptor/cohostedapps.h:16,
                 from ../Adaptor/cohostedapps.c:18:
../Adaptor/WOAppReq.h:41: `WA_MAX_APP_NAME_LENGTH' undeclared here (not in a function)
../Adaptor/WOAppReq.h:42: `WA_MAX_HOST_NAME_LENGTH' undeclared here (not in a function)
../Adaptor/WOAppReq.h:45: `WA_MAX_INSTANCE_NUMBER_LENGTH' undeclared here (not in a function)
.
.
.
```

Solution

1. Remove the directory tree rooted at:
   `/System/Developer/Examples/WebObjects/Source/Adaptors`
2. Reinstall the WebObjectsAdaptors.pkg from the WebObjects 4.5.1 release.
3. Recompile the adaptor source.

Note: This issue is caused by files left behind from a previous version of WebObjects. The WebObjects 4.0.1 adaptor source was included in the DeveloperDocs package from the Mac OS X Server Developer Tools.

AppleWorks 6.1.2: Files Exported to DOS-Formatted Disks Are Not Saved

AppleWorks 6.1.2 may not save a file if you export it using one of the included translators and save it to a DOS-formatted floppy disk.
This article has been archived and is no longer updated by Apple.

Symptom

AppleWorks does not save a file when:

- You choose to export the file using one of the included translators, such as "Save As Word 98 document".
- You choose to save the file onto a DOS-formatted floppy disk.

Warning: If you export the file using a filename that already exists on the disk, the existing file may be deleted, and the new file will not be saved.

Note: This symptom does not occur with DOS-formatted Zip or SuperDisk disks.

Solution

1. Export the file and save it on your computer's hard disk.
2. Copy the file to the floppy disk.

Personal LaserWriter NT: Styled Text with AppleWorks GS

I want to use my Apple IIGS with a Personal LaserWriter NT. How can I get various fonts and styled text (sizes, underline, bold, and so on)?

This article has been archived and is no longer updated by Apple.
Obtain AppleWorks GS from Claris. That version of AppleWorks supports printing using the ROMs in the LaserWriter, giving you various point sizes and font types in PostScript. Without this software you are limited to the one font.

On AppleLink, you can find contact information on a company mentioned in this article by clicking the "Library Index" button in the lower-center of the Tech Info Library search window, then opening the "Third Party Company Directory" folder.

Published Date: Feb 18, 2012

WebObjects: JavaConverter and EOValidation API Changes

This document discribes how WebObjects 5 handles validations differently than WebObjects 4.5.
This article has been archived and is no longer updated by Apple.

Symptom

A validation code used to return void in a WebObjects 4.5 application. However, in the converted WebObjects 5 application, the Java Converter coerces the void into a null causing validation issues.

Solution

The validation mechanism has changed in WebObjects 5.

In WebObjects 4.5 applications written in Objective-C, validation methods return an exception object if the target object is invalid, and receive a pointer to the target as their parameter. If coercion is necessary, the validation method would perform a side effect on its parameter. For applications written in Java, validation methods simply return void. If something is invalid, an EOValidation.Exception is thrown.

In WebObjects 5, this was changed to better accommodate the Java language. There are no side effects on the argument, and the return value is the desired, valid value. If something is invalid, an NSValidation.ValidationException must be thrown. Returning null will be interpreted as value coercion to the null Object reference.

Validation Examples

```
// Objective-C code in WebObjects 4.5

- (NSException *) validateStreetAddress: (NSString *) address;

// Java code in WebObjects 4.5

public void validateStreetAddress(String address) throws EOValidation.Exception;

// Proper conversion in WebObjects 5

// Returns the valid string object or throws NSValidation.ValidationException

// if the street address string is invalid.

public String validateStreetAddress(String address) throws NSValidation.ValidationException;
```
